The answer is: Sort of.

Another post I made mentions that if you know the gain of your DUT you can calculate the noise figure by measuring the noise power output with the input terminated properly. Likewise, I think you could determine the ENR of a noise source by the same method.

Someone else mentioned calculating the noise power of the ENR from the current used. This would give the total noise power, but what is needed is the noise power at a very narrow band of frequencies. If you are trying to measure a receiver, the receiver determines the bandwidth, but with an LNA you need a narrow band detector.

When I was doing the afore mentioned software, I used a FFT power spectrum and made four measurements (DUT with noise source, DUT with out noise source, test receiver with noise source, test receiver without noise source). The FFT provided the narrow band filtering.

Of course, watch out for double sideband fold over in the mixer!

And of course, it was published as a text book. It came out in 1982 from
a text book publisher, Prentice Hall. I seem to recall it carrying a
text book price. I think the only reason many of us took note of it
was because it was by Wes Hayward. I seem to recall it getting coverage
in the ham magazines at the time. I'm not so sure ARRL would have published
a second printing but for the fact that Wes Hayward is well known to hams,
and has had a book or two published by the ARRL.

It covers what it does well, and yes it is a much more involved explanation
than ham books. But it's field is quite limited. It's not so practical,
You can get very detailed explanation of the Colpitts oscillator, but
little about oscillators beyond that.

It's not cutting edge. It wasn't back in 1982, it was supposed to give
a grounding so one could take up other books and get the latest, and it's not
now; I gather there was very minimal changes in the ARRL printing.

This book came up in the other newsgroup in the context of someone wanting
to design a wideband VHF amplifier for his tv set. And no, he was not
advanced in his technical knowledge. It was indeed a lousy suggestion for
his purpose, because not only would he be better off with a cookbook type
book, but Intro to RF Design isn't about a lot of specifics.

On the other hand, the ARRL priting came with a flopppy disk of some basic
programs for designing circuits. I've really only glanced at them, but they
are a bonus for those buying the book.

That was a poor choice of word on my part -- I apologize. I meant "fundamental". Wes explains how things work on a fundamental level. But it isn't a textbook of pure basic theory. It relates working circuits to their fundamental roots.

I took an expensive advanced microwave design short course some years ago. The instructor was a person who'd worked in the field for many years. With disturbing frequency, he would come out with statements I knew to be false and, after some questioning, I discovered that he didn't have any idea of the fundamental (or basic) criteria for oscillation. He'd been designing oscillators for years without really knowing what made them oscillate. This might have been a case of someone who read the "intermediate" texts without ever reading the "fundamental" ones.

This isn't to say that people can't design useful things without fully understanding what they're doing -- I'm convinced that a majority of useful things are created this way. But you can do an awfully lot more if you have a real fundamental understanding of how things work. The most truly creative and innovative engineers I've known have this understanding -- and an intense curiosity about things they don't know.

I guarantee there's plenty of "intermediate" and "advanced" level information in that book, and even without knowing anything of your background, I also guarantee there's plenty of "fundamental" knowledge you missed somewhere along the line and will pick up from this book. If I'm wrong, let me know and I'll buy the book from you. I can always use another copy.

well, said! But isn't this the very frequent feeling one gets from
reading amateur radio magazines? The constructors (I wouldn't use the
word "designer") should have constructed and tested at least 10 equal
constructions, or have similar experience before publishing an idea,
which may later turn out that might not be repeatable

Too often constructions are published when it is a hope rather than
experience that it is a good idea. For somebody it is more important
to use wellknown devices than trying to propose something else

off frequency by 500 Hz.
In the Service Manua, I did not found any way to play whith the
oscillator
or the BFO frequency. >>

Chafik-

I have the older IC-706, which is most likely uses the same IF scheme as yours. My first impression is that the most likely problem is a bad IF Filter.

While older equipment had separately adjustable USB, LSB and CW crystals that were warped by the IF-Shift control, the IC-706 apparently gets its IF converter frequency from a synthesizer that is controlled by the CPU. I don't know how it is warped. It might be done digitally. If it is done by warping the master oscillator, there is a possibility it is misadjusted, except I never found such an IF adjustment procedure in the service manual.

If you happened to have one of the optional filters (or could borrow one), you could see whether the problem follows the filter or the IF-Shift.

Few people appreciate the vast difference between making something that sort of works, once, and a design that can be produced by the thousands with nearly every one working, fully meeting specifications, and being reliable under a wide range of operating conditions. Those of us who have made a living by developing quality products such as test equipment have a full appreciation for this, and go about the design process in a very different manner than a person accustomed to making a one-off circuit for home use.

Many, or most, of the books oriented toward amateurs are written by people who haven't developed the background or discipline to produce reliable, repeatable circuits. Magazine articles are even more in this category. Some circuits found in handbooks have perhaps never been actually built or tested by the author, even in a quantity of one. That's not a condemnation -- after all, this is amateur radio, most offerings are free, and the designs are adequate for a lot of users. Hopefully -- although I'm afraid a bit wishfully -- some builders at least have enough technical know-how to take care of minor design flaws. Nonetheless, it's really a treat when we're given a circuit or an explanation by a truly professional engineer whose approach to circuit design is one of making reliable, repeatable circuits. The chances of a copy of the circuit working the first time, as predicted and claimed, are much higher than for a design built once with little understanding of how it works or what its limitations and weak points are. And the deeper the designer's understanding of the fundamental principles involved, the greater the chance that he's accounted for and designed around potential problems in repeatability and operating environment.

That's one of the reasons I like and heartily recommend Wes' books and other writings. I've known him as a friend and as an engineering colleague for 30 years now. He's one of the very best, and we're lucky to have access to a fraction of what he's learned.

==========

There's far too much blind faith placed in computer programs.

Programs can be no better than their authors who are only fallible human beings.

Good programmers may be able to write practically bug-free programs. But their technical knowledge of the subject matter might be no better than the old-wives who write magazine articles and often contribute to these threads.

Without any intended offence, your Multisim program is worthless to me for the purpose of checking or confirming anything. Why? Because I've never even heard of it! Therefore it carries no weight in attempting to convince me of anything.

Your use of the word "probably" is significant. In the absence of knowledge of the probabilities involved I think it inadvertently displays a measure of lack of confidence in the program.

The only way of accumulating confidence in a computer program is to use it and compare results with what you are already aware of as being true. But if what you are already aware of is untrue and so also is the computer (because you both make the same easily-made mistakes) then your own confidence will be improved but the confidence of others (who may think they know better) in what you say will be undermined.

So, on balance, quoting (or misquoting) computers, measuring instruments, magazine and other articles and contributors to this newsgroup is just a lot of hot air and nobody gets anywhere. Reliabilty depends solely on the confidence which can be placed in the writer.

In extreme cases some authors are worshipped as being infallible such as in ARRL and RSGB handbooks, Terman and Kraus (who I have heard of). Name dropping is better not practiced by name-droppers as a means of supporting and reinforcing their technical arguments.

In the end, statements made by newsgroup contributors are made on their own responsibility without the assistance of free adverts of type numbers of particular measuring instruments, names of computer programs which the great majority of readers have never heard of, the 3 gentlemen who pronounced that 120 radials was a magic number but who forgot to measure ground conductivity, and various worshipped authors whose printing errors and misquoted sermons occasionally disagree with each other, etc.

I'll allow mention of Clerk Maxwell but only by people who have read and understood him. And there's very few of them around. ;o)

Well, I've wandered around and probably said too much. I'm unable to swig wine of any sort tonight because I'm on a 7-day course of anti-biotics and it says on the associated leaflet, in capital letters, alcohol is barred.

Reg.

=========
The brief course leading to the Foundation Licence is meant to enable the
licensee to take part in amateur radio comms in a responsible way ,without
causing harmful interference ...full stop. It also means that he/she is not
fully qualified technically , which is not deemed necessary by the relevant
UK authorities.

While preparing for the next level ,the Intermediate Licence he/she is
increasing his/her technical knowledge and acquires electronic construction
capabilities. He/she also learns to calibrate equipment ,using relevant
instruments.

Finally while preparing for the Full Licence the licensee increases his/her
level of knowledge to comply with international standards set by ITU

This 3 tier system is similar to the US 'ladder climbing AR licensing system
' and is IMHO an excellent way to train radio hobbyists to the required
level and stimulate further personal development.
There is no justification to make any derogatory comments in respect of
Foundation Licence holders.

It's only impossible to form a reliable conclusion when "experts" disagree if your sole source of knowledge and information is from those "experts". That's a bad spot to be in. There are many sources of information available to help you learn about the topic and come to a more informed opinion. That's the solution to your dilemma -- develop a wider range of sources of information and decrease your dependence on the "experts".

Originally developed at Berkeley, SPICE has been commercialized by a number of companies, one of the most popular being PSpice by MicroSim. It's in very wide use, and has been for decades. Do you think that a couple of generations of engineers would have paid several thousand dollars each for software with a reputation of unreliability?

My own experience includes about 30 years designing a variety of test and measurement equipment for several companies, followed by several years doing electronics design as a consultant. In that time, I and my colleages at Tektronix and other companies used SPICE very often. (In fact, recognizing it value, Tek spent a large amount of money and devoted resources to development of its own internal version of SPICE, which included schematic entry and other features before they were available in outside commercial versions.) It's virtually impossible to design an analog or mixed analog-digital integrated circuit without it, and I and my colleagues found it indispensible for many other projects.

You might compare this with Reg's experience with SPICE, if he'll tell you what it is, and see what brought him to make the unequivocal statement about it which he did. I don't personally think he really believes that it's unreliable, though, but was just making one of his characteristic trolls in order to relieve boredom.

When amateur constructors are mentioned, it is not only those who do
strange things. While many large telecommunication and instrument
factories like HP, Tektronic, Siemens, Wandel&Goltermann,
Rohde&Schwartz, LME, Philips, Telettra seem to have certain rules to
follow and you may even see certain ways the different factory solves
the problems, it is some very large companies in Norway, Great
Brittain and elsewhere who make rather strange solutions.

One Italian company forgot to put transient protection over a relay,
and the driver transistor was damaged ever so often. I've maintained
many different transmitters which were almost impossible to tune up
after replacing parts because the impedances changed a lot, adding a
resistor in the base circuit improved on this. A wellknown Norwegian
radiolink manufacturer designed local oscillators in 6-8GHz using
2N3866 with over 1.5W power consumption, a buffer with the same and
operated in class C, the next doubler to 200MHz in class C and a
2N3866 as well, and a 2N3375 in class C. The first and third

transistors were critical and had to be replaced every two years, and the signal on 6cm was so noisy that SM6ESG couldn't find any beat note. He modified the stages to class A, reduced the drive level on all stages and the heat was considerable lower, and at least the oscillator noise very much improved

So, one shouldn't only blame the amateurs for bad constructors, but sometime the manufacturers may even be worse

73,
Jan-Martin

3158. Tube current sink

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-10-17 04:19:54 UTC
From: Prune <bobysgotguns@yahoo.com>
Message-ID: <Xns9584D9015D441Gormenghast@64.59.144.76>
Source record: 22592

What's the best tube type to use for a voltage controlled current sink, with respect to linearity?

I am building plasma tweeters, with a DC glow discharge modulated by audio (similar to US patent 4,219,705, but I'm using microhollow discharges (MHCD) as cathodes for the larger discharge to remove cathode fall instabilities; this technique was unknown during the time of that patent). My power supply is 2700 V at 400 mA (200 mA for each of two channels for a stereo setup), ripple filtered to 0.01 V. I'm hoping to have the discharge drop most of the voltage, and the driving device a lesser portion. The driver needs to be a voltage controlled current sink at the plasma cathode (the plasma anode is the high voltage). Since the audio modulation is only a few percent of the bias, less than 20 mA, essentially I'm concerned with linearity in a small range around the average operating point. I need to know what's the best tube type to use in terms of the sound quality, and in what configuration (grounded cathode or grid, etc.). Most current drives use pentodes, but I've been told a triode is more linear.

3159. Re: Wes Hayward's "other" book...

I obviously can't speak for the Italian or Norwegian companies you mention, but I do have the direct experience of 17 years of circuit design and project engineering management at Tektronix. It's hard to imagine experiences like yours happening with Tek equipment.

During the time I worked there, and presumably up to the present, Tek had what they called the "phase" system. The engineers would do their very best to design the product to meet all the advertised specifications, plus additional non-advertised in-house specs. These included temperature, vibration, shock, humidity and other environmental specs; certification by various safety agencies; and EMC requirements, in addition to detailed electrical performance specs.

When this design was complete, a meeting was held. Attendees included representatives from design engineering, marketing, product safety, component and evaluation engineering, and others. Only by consensus of this group was the milestone declared to have been completed.

This was just the beginning, though, of the first phase, called "A Phase". A number of instruments were built, typically around 25 to 50. Some were sent to the environmental lab to test performance over the range of specified environmental conditions. Others were shaken and shocked. Others were studded with temperature probes and tested for excessive temperature at many internal points. A few were put on accelerated long-term reliability testing at a greatly elevated temperature. Some were cycled on and off at high temperature. The design was carefully analyzed by the evaluation engineering group, looking for overstressed components. And many of the units were tested against the full specification list, to insure that they fully met every spec.

During this phase, many problems were of course found and fixed. The engineers would generate change orders describing the fixes, and the test units were modified accordingly.

When it was believed that the units all met the many requirements, another milestone meeting was held. Again if the attendees agreed, the milestone was declared met, and "B Phase" began.

B Phase was largely a re-run of A Phase. Again, a sizeable number of instruments were built and fully tested. Problems which were found were corrected. Only at the end of this phase was production started.

Production often started with a pilot build. The first hundred or so instruments were given extra scrutiny, temperature cycled, and otherwise tested in a way to overstress them. These instruments normally became demo units for the sales force, and some were retained by engineering

for internal use.

After pilot production, volume shipment finally commenced. Some large companies required an incoming inspection test where every one of the electrical performance specifications was checked, and the instrument rejected if any failed. I once had the job of collecting test equipment and writing a procedure for customers to use for testing our 50 GHz bandwidth sampling head to specification, and it was very difficult to find equipment capable of verifying the performance. We weren't able to claim 60 GHz bandwidth even though we were pretty sure our units would do it, because we couldn't find a way for us or the customer to verify it at the time.

After the units were in production, each field service center kept records of repairs, and which components failed. They were sorted by circuit number (e.g. Q123) and part number, as well as by instrument and board. If any part showed a high failure rate, the design was modified and future instruments were built using the new design.

I know that other quality manufacturers have similar development systems.

That's why a Tektronix instrument costs a lot more than some others. The existence of companies putting out the shoddy sort of stuff you mention shows that some people are willing to trade quality for price. That's their choice.

But the environment I described is the one I, and Wes, are accustomed to, and it's what our designs had to get through.

Some years back, after retirement, I bought out of curiosity a copy of Electronics Work Bench. It was and still is the only such program I have ever had my hands on. I think it arrived on a collection of floppies.

After a few days curiosity was satisfied. Then I junked it.

All programs have bugs. I only asked why people think it IS reliable.

I am aware of its existence only from the frequent mentions made on newsgroups.

Why do the arguments continue after Spice has arbitrated?

I have no reason to think Roy's opinion of Spice is anything other than true.

But whatever it is, it is not a device intended to be used as a means of instructing learners on the theory of electrical circuits. All programs have many limitations which eventually always become serious and which are UNKNOWN to the user. Very often they are unknown even to the programmer. Limitations should not be allowed to cross over the borders of knowledge. Programs should not be worshipped for always telling the gospel truth. They don't.

For example, a sensible circuit designer invariably checks the output of a program by making a hardware prototype - or several. Why? Because he trusts neither himself nor the program!

Source record: 22596

It's been a while since I've done this. But one way to realize a band stop filter is to begin with a lowpass prototype of the desired response (Butterworth, Chebyshev, etc.). Then add a capacitance in parallel with each inductance of the lowpass, of value 1/(w0^2 * L), and an inductance in series with each capacitance of the network, of value 1/(w0^2 * C). Beginning with a common series L - shunt C lowpass, this results in series-connected parallel resonant circuits with shunt series resonant circuits in between. Intuitively, the topology is correct in that you'll have zeros due to both the series and shunt networks, and the response will be unity at DC and infinite frequency. Another topology which would work is alternating shunt series resonant circuits and series parallel resonant circuits. The topology you describe can't possibly work since the coupling capacitor prevents unity response at DC.

This methodology doesn't account for inductor loss, as Wes' analysis does. You'll find the necessary information about this in Zverev, and making use of it will give you a real appreciation for the programs now available for the purpose.

The Elsie filter synthesis program has a bandstop filter design option. I
just tried it and it works OK. None of the designs are top-coupled
resonators, though.

Just an explanation to the person who asked:

Reg is one of the few people in the world who have no use for a spice simulator. He writes lots of very good calculation programs and knows electronics like he had a built-in electronics simulator in his brain. He has studied electronics during a long life and knows what he talks about.

For other people though, a spice simulator can be very useful.

Multisim has a very bad reputation because is has a lot of bugs.
The best version of EWB is 5.c
After that version multisim replaced the central parts of the program and the new program had a lot of problems.

Nobody uses later versions of multisim, so we do not know if they have solved the bugs yet.

EWB 5 is used by beginners, because it has a very good user interface.
But even EWB 5 is not regarded as a good spice simulator.

Professionals often like the freeware spice simulator Switchercad3 from Linear Technology. http://www.linear.com/company/software.jsp

I use EWB 5.c myself, because it is good enough for my purposes, and it is a lot easier to work with than Switchercad3. But I use Switchercad3 sometimes too, because people in newsgroups often give a circuit in switchercad's text file format.

Another advantage for EWB is that it has been around a while, so there are many add-ons to the program, like a converter from EWB circuit to an Eagle layout (Eagle is a freeware layout program for circuit boards). Translation programs from ewb to standard netlist is also available.

After multisim changed the program there was a big wave of protests among the EWB users and buyers. New buyers demanded to get a copy of the old working program when they bought the new version, and Multisim accepted

that and delivered a EWB version 5c for free, on demand, to all buyers of the new program.

I don't know if they still do.

Question - what is the internal modelling technique used
by these various programs, and can we produce our own package?

Is it based upon successive delta-time increments, and if so, what
is the increment? What prompted the last question is an attempt
I made to create a sine-wave generator using the identity that
sin dTheta = dTheta, but I had to go for an _extremely_ small
value of dTheta (ISTR 10^ -18) before getting anything like a
decent sine wave, and even that degenerated after a few cycles.

So, these circuit simulators - what is their underlying technique
for circuit simulation?

Most of them (exceptions being the harmonic balance types for RF) use
the old Berkeley Spice engine developed by the good folks at the
eponymous university. The simulation package authors just adapt the
engine with their own preferences WRT to features, GUI, gimmicks etc.
So yeah, you can certainly come up with your own flavor of Spice just
by adapting the basic Berkeley engine to your tastes. It's highly
unlikely to be worth the effort, though. There's already a spice out
there for everyone - if you can find the right one for you.

apart from Tek and certain others which Roy describes, I believe that
some economists look at the balance between number of components used
and trade-off in production, so much more equipment would pass the
control if certain components were added.

What I actually meant, but perhaps didn't fully express was that you
may study the circuit diagrams and have a feeling which manufacturer
has designed it, they follow certain techniques and technical
management.

On the other hand one may experience that HP and Tek uses some extra
components which are difficult for the average constructor to explain
or understand the function for, and one may experience that even among
the amateurs somebody manage some technique which almost nobody else
can copy - not even very experienced persons, may I mention SM5BZR
Leif's techniques, it is many constructions, they may look so easy,
but one often need some more deeper understanding to succeed, what
say's G3SEK?

I'm not interested in someone else's engine - that's not the
way of the _REAL_ Radio Ham

It is _ALWAYS_ worth the effort to do things for yourself - that
is the essence of _REAL_ Ham Radio - it is the CBer and the
CBer-Masquerading-As-A-Radio-Ham who buy things
off-the -shelf!

It's been the case in Britland for many years now, that if you
want info to build modern gear, then buy the ARRL handbooks.
OTOH, if you want a mediocre book that is many
years out of date and seems to owe more to self-congratulation than
it does to technical excellence, then go for the RSCB offering. Odd, really,
when you consider that the RSCB is a publishing corporation.

I do not agree, and soon the RSGB is the only IARU organization I
support, have been a member from january 74. They now contribute with
a lot of useful material, but it was different earlier, as one had the
feeling that high-ranked persons or duke and knights with outdated
experience was telling you what to do.

But for Radcom, I must admit that I mainly read G3VA's "Technical
topics"

My radio club was Worcester &DARC, suppose it is not so much activity
there now....

I don't have any personal experience of copying Leif's designs (assuming this is SM5BSZ we're talking about) but they have been widely copied. It just takes everyone else a whole lot longer... so he's still way out ahead.

I don't know the best tube for your application, but I _can_ tell you that a triode has a quite significantly lower plate resistance than a pentode; if you really need the current to be independent of plate voltage then a triode without heavy cathode degeneration isn't the way to go.

I believe that triodes are more linear when driving a resistive load exactly because of this lower plate impedance -- if you hold the plate voltage constant then the plate current vs. grid voltage relationship isn't any better than a pentode, but if you allow the plate voltage to vary it provides internal feedback on the tube current.

Hopefully you'll get someone who'll give you a more definitive answer. Perhaps looking for a newsgroup that involves audio, rather than radio, homebrewing will help.

This is to be expected. The engineers who work at the job all day, every day, know and understand a lot more about the circuits they're designing than someone to whom it's only a hobby.

And, considering the incredible time and effort that goes into the design of each product, Tektronix and similar companies can't afford to be making instruments that can be perfectly copied within days. I never saw any conscious effort to obscure a design, but the normal process of developing state-of-the-art equipment required use of techniques out of the reach of amateurs or even most manufacturing companies. Let me give you just a few examples.

1. Circuit board layout becomes critical for many high performance circuits, and sometimes several iterations are required before all problems are solved. There are also mechanical considerations such as maintaining necessary air flow. In a product I worked on, we had to solder the turns of a delay line together to reduce coupling from a CRT deflection circuit. In another, the ground was broken in a critical point to interrupt ground current flow.

2. Design techniques are used which aren't well known outside the industry. For example, look at the schematic of the vertical amplifiers in older Tek analog scopes. You'll find series RC combinations, sometimes with a thermistor as the R, between the emitters of the differential stage transistors. These served two functions. One was to compensate for the delay line loss which increases as the square root of frequency. The other is to compensate for thermals -- the fact that a common-emitter stage gain changes as the transistor heats up in response to a signal voltage change. This can usually be ignored in a time-domain application, but can cause serious distortion of a voltage step or other time-domain waveform. Changing the transistor type or sometimes even its package type changes the compensation requirements.

3. Component selection and design are often critical, as is material selection. As an example, some high impedance attenuators are built on special circuit board material such as polysulfone, because of a nonlinear property of FR4 and other materials called "hook" which causes signal distortion.

4. Manufacturing techniques. The list of these is almost endless. It becomes a major determining factor in circuit performance particularly at very high frequencies, such as the 20 - 50 GHz sampling heads I helped design.

I recall showing a photomicrograph of a new sampling head to a company which was very sensitive to security, and telling the surprised

engineers that I'd be happy to give them a copy. I also told them truthfully that even if I gave them the schematic and parts list, they still wouldn't be able to build it. I'd guess that a competing company with world-class engineers might be able to do so in about a year. There were just too many special and selected components and manufacturing tricks.

So it's wishful thinking to believe that you can duplicate one of these high-performance circuits by soldering parts together from a circuit diagram. There's a very lot that goes into these products that most people have no idea of.

So, 1080 watts of heat dissapation or more just to hear high frequencies???

Is there no other more sensible use of energy for you?? It would seem that there are several types of tweeter choices that require no energy other than audio drive that would still perform 10 times better than your ears ability to determine distortion, and at least 5 times better than any pickup devices ability to change input sounds into electrical output.

If you really want to waste energy as heat dissapation, and impress your audiopill lacky buddies, use a 304TL, or 304TH. 300 watts of plate capacity with a super high perveance that looks like a plate to heater short if you drive the grids a little bit positive.

You should turn yourself in to the EnergyStar folks, and do about 100 hours of community service. The crime??? More imagination than true ability to determine accurate sound reproduction quality.

my favorite commercial design "oops" was a pricey multi-port TTY
(teletype) i/o board for the then new Nova 4/X minicomputer (data
general). Worked great, as long as you only used video terminals
emulating a TTY on a current loop. Put on a _real_ teletype, and you
quickly fried the board, every time. No protection against counter-EMF.
After two board exchanges (in warranty, thankfully), we finally just
put in opto-isolators on our own TTY lines and it worked thereafter. ;-)

The side arms are OK as series resonators but your middle C needs changing
(transforming) into a C+L parallel resonator.

The way to go is firstly design a prototype low pass filter. Then transform
it to its high pass equivalent. Then transform to the band stop design.

> multiply RMS voltage by RMS current or resistance is an AVERAGE value,
> not an RMS value.

I completely agree about RMS 'power'. RMS applies to a voltage or
current waveform.

Caveat: you cannot simply multiply RMS voltage by RMS current unless
you have a purely resistive load. Oddly enough, if the load is a
fixed resistance (measured as a conductance G) in parallel with a
reactance then the E_rms^2 * G (E_rms^2/R when purely resistive)
value continues to apply. When it is a fixed resistance in series
with a reactance, I_rms^2 * R continues to apply. And these extend
to the nonsinusoidal case as well, again under the restrictions
given above (fixed G in the first case, fixed R in the second).

> This may seem trivial but it becomes important when trying to convert
> from one form to another. Using the wrong notation can give you wrong
> answers.
>
> As to the above, the average voltage or current of a sine wave is 50%
> of the peak.

Actually, it is .6366 times the peak. The averaging is done continuously
over the positive half cycle of the sine wave, and is essentially the area
under the sine curve divided by the length of the half-cycle (2/3.14159,
or, if you calculated in degrees, 114.592/180).

The true average value of a sine curve is to average over a full cycle,
but is not very interesting: it's zero. The .6366 number is useful
because it is what a VOM typically measures - average DC voltage
after passing through a full-wave rectifier and before applying a scale
factor of .7071/.6366 to produce E_rms - all based on the assumption of
a sinewave input.

Average value of voltage or current waveform is of limited use; but
RMS value is directly related to the ability to deliver power to a

resistive load.

> The rms value of a sine wave is .707 of the peak voltage or current.
> If you multiply .707 (rms voltage) by .707 (rms current) you get .5 or
> 50%. This is AVERAGE. It is no longer an rms value.
>
> By the way, the definition of peak envelope power (PEP) is: "The
> average power contained in one RF cycle at the crest of the
> modulation envelope". (note that the definition says "AVERAGE power"
> not RMS power)

The average power is in fact all that is of interest in AC circuits,
and is the average over time of "instantaneous power" E*I.

If you do not use average power you have to deal with the fact that
reactances accept power during half of the cycle and then feed it
back during the other half; and for nonsinusoidal waveforms do the
same but in not so regular a pattern.

PEP is just averaging over the shortest reasonable interval (one
cycle of the carrier frequency), then keeping only the largest
such value seen. Useful to regulators because it is a measure
of your maximum capacity to interfere with other signals.

> So, 1080 watts of heat dissapation or more just to hear high
> frequencies???

Hey, if I'm paying for it, why not. You sound like one of those nutty environmental activists. You know the types, that would force decreased energy use down people's throats so that their pet projects like wind and solar power can provide enough energy, thus completely ignoring the fact that most of the world population in third world and developing countries will have its per capita energy use jump orders of magnitude to approach that of developed countries in the coming decades -- you'd need to cover the planet with windmills to provide enough. And for what? Even if fusion doesn't work out (and aparently the ITER project members including the US, EU, Japan, Russia, Singapore and others think it will, and have already planned out the first over-unity reactor to begin construction within a few years; see iter.org), the existing technology of fission breeder reactors can provide essentially unlimited power even with the current minable supply of ~7x10^6 tonnes of uranium. Energy shortages are artificial and politically imposed.

> that there are several types of tweeter choices that require no energy
> other than audio drive that would still perform 10 times better than
> your ears ability to determine distortion, and at least 5 times better

Where did that number come from? THD measurements generally do not correlate with human perception. For example, see http://www.gedlee.com/distortion_perception.htm and the numbers in the table there. Better yet, check out their papers in the Audio Engineering Society; you can find other similar developments by searching the Web. The specific types of distortion are far more important than some summary statistic like THD or IMD. The analogy is a population with an unusual distribution, and using an arithmetic mean to describe it -- say some third world village, and 50 people in it make $1/day, and 1 makes $100. Obvioiusly the mean, being almost $3, is a pretty poor descriptor of rich the villagers are. The point is that this far there is a lack of a good metric correlating fully with human perception of audio quality. This is why, for example, when some institution or company is developing a new audio (likewise for video) compression codec, blind testing with human subjects is always performed during evaluation. I'm not to say that there isn't tons of snake oil and over-the-top nonsense and scams caused by marketing departments in high-end audio business (that's why I've built every component of my system except the DVD player). But the people that go to the other extreme and say that everything sounds the same are also

wrong. Initially people thought jitter in early CD players was a non-issue, because being measured in picoseconds, it was thought to be imperceptible. This turned out completely wrong, and the technology had to be corrected. Look now at TI and Cirrus and Analog Devices datasheets for DACs and ASRCs, and they mention jitter quite a lot. Indeed, it turned out that poor disc mastering can introduce jitter that sounded so bad that recently under complaints from artists Sony changed some manufacturing steps to eliminate the problem. Another example of people not measuring the right things is that discontinuities in the phase distortion screw up perception of direction. And even ultra-conservative audio engineers like D. Self has admitted that electrolytic capacitors cause distortion, and that thermal distortion exists at least in integrated circuit amplifiers (and this is an example of a type of distortion that does not affect THD and IMD numbers). And so on. Finally, it is of note that a single blind test that shows no result is no proof that a difference is inaudible. For statistical significance, a number of trials is needed and there are very very few examples of such studies in audio perception.

> than any pickup devices ability to change input sounds into electrical
> output.

Yes. But why add more distortion than there already is? Also, formats like SACD and DVD-Audio are often digitized directly from the original master tapes (in the case of non-new recordings), thus doing away with some of the damage that has been done. These formats also use 24-bit encoding to deal with the problem that 16-bit audio does not achieve the full dynamic range that the ear is capable of perceiving (technically 16 bits are enough, but in practice actual 16-bit equipment is not able to achieve the theoretical maximum).

> If you really want to waste energy as heat dissapation, and impress
> your audiopill lacky buddies

LOL, I have no audiophile buddies, other than some people I argue with on online forums. The funny thing is that usually I'm arguing the other side, the skeptic. The truth is, I may very well not be able to tell a difference between this and a quality dynamic or electrostatic tweeter. On the other hand, I'm sure decent tweeters existed during the 1980s when Hill's Plasmatronic speakers were made, and Hill is a PhD working for the military on plasma and laser reasearch, so I think he's got his feet firmly planted in the real world. Also, how do I know that even if some change I make to my system that by itself makes a difference so small I can't hear it, multiple changes' cumulative effect won't be detectable? And finally, even if it makes no difference, it's the coolness factor of outrageous upgrades (someone called it audiophile equipment fetishism). Even though I know for sure I couldn't hear the difference between cables, I still made interconnects out of fine silver and teflon. I know full well any conductor will sound the same, and that dielectric absorption is not an issue at audio frequencies, so the teflon is pointless. But that's not the point. And even with cables, it turns out resistance is not all that matters. For example, consider the case of a passive preamplifier (or a

potentiometer volume control at the output stage of the source) feeding a power amp with a not very high input impedance. A number of commercial interconnects have sufficient capacitance to affect the audible frequency response in this situation.

> use a 304TL, or 304TH. 300 watts of plate capacity

I don't need that much dissipation ability. What about a 152TL so I can save some money? Would that have sufficent perveance? In the end, all I care about is linearity within a range of ten or so mA around the operating point of about 180 mA. Would these types of triodes be better than pentodes? And finally, I've seen these TL and TH suffixes often, but I never figured out what's the difference (the datasheets look about the same).

I'm not sure who the "we" is in your statement, but it certainly doesn't include people who understand the concepts and mathematics involved. The problem with your approach is that there *is* such as thing as RMS power (as I described in an earlier posting), and it is *not* the amount that gives the same heating effect as the same amount of DC power. So while you may think of RMS power in this way, your thinking is wrong.

I can calculate my RMS speed in going from point A to point B. But it isn't equal to the distance I went divided by the time it took to get there (unless, of course, I went the whole way at a constant speed) -- for exactly the same reason that the RMS power isn't the equivalent heating power. You can think of the RMS speed as being the distance divided by the time, but it isn't, and your thinking doesn't make it so. And that also doesn't make the RMS speed a useful value.

In article <Xns9584D9015D441Gormenghast@64.59.144.76>, bobysgotguns@yahoo.com says...

Sorry for the top post, but here is the TL/TH deal

TL triode low gain, generally about 10
TH triode high gain, generally 40 to 100
Why the 304TL or 304TH, and not the others?? The 304TH is 4 75TH triodes in parallel in one bottle, and the perveance is so far above and beyond anything except perhaps a television horizontal output sweep tube tetrode, or pentode. The sweep tubes probably won't have enough dissapation unless you parallel them up.

Steve (Evans),
Correct me if I am wrong (like I need to say this here, eh?)
I believe the underlying basis is the collection of loop / node equations used (by Engineers) to model circuits. We know the behavior of resistors, inductors and capacitors and have mathematical models for them. To this we add the active devices, etc. and develop an "engine" which does all the calculations for us. [[we used to do them by hand/slide rule -- yes, I am included in this we]]. These loop and node equations provide us with a mathematical model of the behavior of electronic circuits. If done carefully, this is a general purpose model which applies to all the situations for which our component models are valid.
Some time later there were bare engines into which we had to type the part values and node numbers (the sane things you can see in printouts from Spice). As computers got more powerful, schematic entry was developed. I believe these programs to be very useful, but as with any model or simulation, it is best to understand the limitations.
Thre is an alternate method. It is also possible to derive equations for each type of situation and use these calculations each time you need to solve that type of problem. I am sure you are familiar with the equations for things such as parallel capacitors and resonance and so forth. These are specific solutions of the properties of components in those specific circuits.
From some postings here I get the idea that Reg is providing various "calculators" in the form of computer programs for hams to use to solve/design various circuits. Not one thing wrong with either this or the

general type of software...Except that the limitations argument applies to all calculations and it is our responsibility to determine whether or not our situation is adequately covered by a particular math model.
I am also not familiar with the programs mentioned here (except to have heard the names), except for OrCad's PSpice ver 9, which is relatively easy to use (for me) and provides results adequate for my purposes--not to mention the fact that I was given a CD with the student sample version on it). I was introduced to is by the department chair at the county college where I was asked to teach some classes and like it. I just draw a circuit and can then do various forms of analysis. I modeled a recent project and all worked the first time when I assembled the one and only unit. It was a simple RS-232 to Kenwood TH-F6A handheld interface.

I agree 100% with Reg in that a circuit simulation program is not intended to *teach* circuit theory, That needs to come first, then the simulation tool can help us gain a better understanding by letting us try out the things we learn and "see" them happen with out having to collect all the parts and wire it up. I find it much faster to "assemble" a PSpice circuit and test my design ideas than go into my basement and collecting all the parts.

BTW it *IS* the cap AND diode which cause the negative voltage in the coupling circuit described so long ago...

Airy,
While I applaud your desire to understand how these "engines" work and perhaps build your own, I suggest that it is a most formidable task by any measure. If you understand the concept of loop and node equations then you know the math. Now figure out how to write software to handle any circuit and you have it...then there is the user interface...(what I believe is the most important [and most difficult to do well] part of any program)

73,

When solving node/loop equations manually, it's generally necessary to resort to phasor analysis with its underlying assumptions, or Laplace transforms. The latter does have the capability of producing a time response. But the solution requires finding the inverse transform, a process similar to integration in that there's no single direct rule, and often it's impossible to find a solution except for simple cases.

Computers can be programmed to solve complex problems numerically, using fundamental time-domain current/voltage relationships (such as the relationship V(t) = L di/dt for an inductor, or even more generally, V(t) = L di/dt + I dl/dt for a time-varying inductance). This is basically what SPICE does, and it's able to easily solve problems which are simply not possible to do manually, either because of the enormous time that would be required, or the impossibility of finding a reverse Laplace transform -- or its equivalent, the solution to a high-order differential equation if Laplace transforms aren't used. A google search on 'SPICE "time step" equations' brought a number of hits. I'm sure you can find an adequate explanation of the inner workings of SPICE among them.

While the discussion is interesting, one needs to consider the purpose. For a pure sine wave, certain relationships are stable and hold true. For a complex waveform, like voice, the relationship between peak power and average/RMS power not a straightforward relationship.

<< I would like to homebrew a 20mfd/4'000v capacitor for linear power supply. >>

David-

My first thought was to take ten 200mfd/450v electrolytics and wire them in series, each capacitor with a parallel resistor to ensure equal voltage division.

The problem is that you may not find a single electrolytic capacitor with that high a voltage. Even if an electrolytic's voltage is determined by stressing them to a higher value, there may be a limit well below 4KV.

You need to do a lot of research in physics and/or chemistry if you're serious about homebrewing such an electrolytic. The usual approach is to construct such a high voltage capacitor using a porous oil-soaked dielectric material ("oil filled capacitor").

Over 80 mods now listed plus a dozen on the To Do or Wish List. More mods than for any other general coverage receiver! Thoroughly documented.

If you like to tinker with radios, I know of no other recent model that lends itself to as much fun in this arena as the DX-394. Great platform for learning radio-electronics. Always 1 or more FA on eBay.

Active & friendly user community now with over 700 members. Some members are keen short wave listeners; others are into AM DXing and a few enjoy long wave. Many experiment with
antennas and some are ardent modifiers - customising and souping up the rig as hot rodders would do with cars. You'll find lots to interest you and help get the most out of your radio.

All here at:
http://groups.yahoo.com/group/RADIOSHACKDX394/

It has the most complete collection of modifications, usage tips, links to related websites, documentation, and photos along with a user survey and a message forum (2877 messages archived) to help you get the most pleasure and DX out of your Realistic / Radio Shack DX-394, DX394, DX 394.

Yes.

> So if you have 100 VRMS and 1 ARMS, how much power is the resistor
> dissipating? Just pure power in terms of heat generation, forget
> whether it's RMS or anything else. How many watts?

100 watts. This is the average power. (The RMS power is about 122.5 watts, if I did the integration right -- corrections are welcome. RMS power is calculated from the instantaneous power exactly like RMS voltage or current is calculated from instantaneous voltage or current.)

> And now the real question: How much DC voltage would you have to apply
> to the resistor to get exactly the same power dissipation?

100 volts. The dissipation would be 100 watts.

> Breathlessly awaiting,

I would hope that any Technician or higher class amateur could immediately answer those questions, no waiting required.

The problem people seem to be having is the feeling (or, I'm afraid in some cases, certainty) that an RMS value of a quantity times an RMS value of another quantity HAS TO BE the RMS value of the product of the quantities. But it isn't. Here's something you can check on your calculator: Take sin(5 degrees) times sin(10 degrees). Is the product of the two equal to sin(50 degrees)? While the product assumption works for some functions, such as square and square root for example, it doesn't

work for others, like RMS and sine.

Unfortunately, if you (any reader, not Bill personally) aren't able to follow the mathematics involved in calculating RMS and average values (which I posted in brief form a short while ago), this is bound to remain something of a mystery to you, and it looks like you're left with four choices:

1. Hang tightly to a mistaken idea about the meaning of RMS and average, and ignore or resist any explanation that contradicts them. This will include explanations in any textbook.

2. Learn enough math to understand the definitions of average and RMS, which should make the explanations understandable.

3. Assume that I and the textbook authors know what we're talking about and believe us, without really understanding why.

4. Find a textbook oriented toward people without a very strong math background, which hopefully can explain it in terms you can understand.

The fourth choice is probably the best for people who are really interested in learning and can't devote the time necessary to learn the math. The main problem with the first choice is that you'll be likely to pass the misconceptions on to others. But the choice is yours.

Source record: 22641

Let me add one more comment that will hopefully help in understanding this.

I think I might have identified another misconception that might be contributing to the confusion. That misconception is that the RMS value of a waveform is the "equivalent" or "heating" value. This leads to the mistaken notion that the RMS value of the power must be the "equivalent" or "heating" value.

Voltage and current, by themselves, don't do any heating. Heating takes power. And the amount of heating is the determined by the average power. If two different power waveforms have the same average value, they'll create the same amount of heat and otherwise do the same amount of work, even if their RMS values are different.

So what's the whole thing about RMS? The only importance of RMS is that when you multiply the RMS values of two waveforms together (such as V * V, I * I, or V * I), you get the average of the product of the two. That is, RMS(i) * RMS(v) = Avg(i * v), where i and v are the instantaneous values of the current and voltage, and i * v is the instantaneous power. Likewise, RMS(v) * RMS(v) / R = Avg(v*v/R) and RMS(i) * RMS(i) * R = Avg(i*i*R). In fact, RMS(x) * RMS(y) = Avg(x * y) where x and y can be any periodic waveforms or quantities. (I derived these mathematically in an earlier posting.) So we calculate the RMS values of voltage and current only so we can use them to calculate the average power -- not because the RMS value of any waveform is its "equivalent" or "heating" value -- which it isn't.

An electron beam in a vacuum can flow current without any voltage drop,
as can a superconductor. Granted, these are not everyday occurrences,
but they _do_ occur.

The real point that Roy is talking about is that whenever a voltage drop
occurs simultaneously with a current there is power being consumed --
and if it isn't coming out of the system as some other form of power
then it's being dissipated as heat.

I agree. On the one had we've had a pillar we'd always accepted
knocked away by Roy; on the other hand, it was Roy who knocked it
away. Had it been anyone else I'd have dismissed them as a nutter.

>I will QRT for now, but thanks for taking the time to explain. I mean

As I'm sure we all do. If this is a misconception it must be an
extremely widespread one. I've found a reference to RMS power and how
it's calculated in 'Practical Radio Frequency Test & Measurement'
(Newnes) and have posted the relevant page here:

Sure, current can be present without voltage (in a short circuit) just as easily as voltage can be present without current (in an open circuit). But what I meant was that the value of voltage doesn't determine heating, nor does the value of current. It's the value of power that does.

I have no idea who taught that to you, since the definition of RMS is in its very name (the square Root of the Mean of the Square of the function). It's your choice to ignore the accepted definition. I can only hope you don't teach your mistaken idea to others, who will then someday say the same thing.

> I will QRT for now, but thanks for taking the time to explain. I mean

I really appreciate the compliment, and will do my best to try and
deserve it.

Please look very carefully at the diagram at the URL you've posted, and
notice that it's a voltage waveform (see the labeling of the vertical
axis). Then read the text very carefully. Neither the diagram nor the
text contradict what I've said. If you think it does, post the reason
why, and I'll try to clear it up.

My statements about voltage and current referred to ideal circuits, which are immensely useful in gaining understanding of fundamental circuit operation. One can argue for a long time about how perfect a real circuit can be made, and I won't get into that. I hope I made my point without the need to.

Okay, here's the bit that you seem to take exception to (it's spread
over both pages):

"We can define the real power in an AC circuit as the equivalent DC
power that would produce the same amout of heating in a resistive load
as the applied AC waveform. [In a purely resistive load] we can use
the root mean square (RMS) values (Vrms and Irms) to find this
equivalent or RMS power."

Then the equation "P = Vrms x Irms"

Where "P" here explicitly refers to RMS power.

This is something you have stated clearly that you disagree with.

Hi Paul,

Motorola used to produce modules like that. I don't know if they still
do, or if it was all transferred to one of their spin-offs.

Paul, I apologize. My browser showed only the first of the two pages, and I didn't realize that the second was there. While looking for the quotation I found that the second page was simply scrolled off screen.

Yes, there is one thing (on that second page) I do disagree with the author on, that the equivalent power, the product of Vrms and Irms, is "RMS" power. I did a brief web search to find out who the author was so I could contact him about that, and discovered that it's Joe Carr. Unfortunately, he died a short time ago.

Maybe my suggestion about looking in non-mathematical texts for an explanation wasn't such a good idea. It appears that some of the authors of those texts don't fully understand the math either. I'll have to say that you certainly have provided some evidence as to how widespread the misconception is. Next time I'm downtown at Powell's Technical Bookstore, I'll leaf through a few volumes oriented toward technicians and see just how bad it is. All I have on my bookshelf in the way of basic circuit analysis texts is two (Pearson and Maler, and Van Valkenburg) which are intended for beginning engineering students, and they of course both have it right. A popular elementary physics text which I have, Weidner & Sells, _Elementary Classical Physics_, Vol. 2, succinctly summarizes (p. 913): "Thus, the average rate at which thermal energy is dissipated in the resistor is the product of the rms voltage across it and the rms current through it." This follows immediately below an equation showing the calculation of pav from the classical definition of average which I posted some time ago.

In response to the question about Vrms, Irms, and equivalent power, I said that when Vrms = 100 volts and Irms = 1 amp, Pavg = 100 watts and Prms is about 122.5 watts. I haven't had any previous occasion to calculate RMS power, so I might have made a mistake. According to my calculation, for sinusoidal voltage and current, the RMS power equals the average power (which is Vrms X Irms when the load is resistive) times the square root of 1.5. Surely some of the readers of this group can handle the calculus involved in the calculation -- it's at the level taught to freshman engineering students, and now often taught in high school. The calculation isn't hard, but it's a little tedious, so there's ample opportunity to make a mistake. I'd very much appreciate if one of you would take a few minutes and double-check my calculation. Or check it with Mathcad or a similar program. I'll be glad to get you started if you'll email me. And I'll be glad to post a correction if I did make a mistake.

Hi Group,

I now have an old 1-meter disk with a LNA for primestar. Anyone tell me about the frequency range of the LNA and any amateur applications?

I read Terry's work again, the comments and links.

White noise generated with the B-E junction of a high
Ft transistor, B-E junction is a zener.
If you downconvert above 100kHz, that's where white
noise starts, and display it with your soundcard you
"should" get a flat respons.
The methods where right, the spectrum used was too
low.
Add zener noise to your soundcard and you get pink
noise, because at low frequenties the noise behavior
is always pink + the 1/f semiconductor flicker noise.
You can justify it, but that's manmade white noise.
If I was interested in random numbers, I would use
real white noise, real random.
The keyword here is downconvert in KISS concept,
simple as possible.
Semiconductors produce also white noise.
If you can't display white noise, that does not mean
the noise generator produces non.
I would not trust my sound card at all, because with no
input the FFT shows pink noise, ok,at very low level,
but its added to your not anymore random signal.
I have tried Spectran FFT software.
Peaks from noise floor up to 20dB in the range of zero
to hundred hertz.
The computer is full of signals inside, that's not random
compared to white noise.
If you are measuring relative great signals, the little noise
does not improve the S/N ratio so much that you cannot
copy the signal anymore.
But random noise added with little pink noise is no longer
random, how small the error is, especially if the error is only
at a specifiek part of the spectum.
Maybe a professional A/D chip can do the job ?
Unfortunate a spectrum analyzer can show you the white noise,
but cannot make numbers out of it.
To make numbers out of it is the difficulty I think, not to get
white noise.
The analog world and digital world have a " love and hate"
relationship, sometimes they work fine together,
sometimes not.
I don't say the above statements are right, its just how I think
about the experiments at my point of view.

3222. Re: 2.4Ghz PA module recommendation required

Is it for Wi-Fi network?

It could be a tough call. According to FCC regulations we not supposed to
transmit that much, hence readily available products are typicaly limited to
1 Wt, like this one:
http://www.connectronics.com/fidelity%20comtech/

Once I was thinking to use something exotic, like this 1177H10 TVT:
http://www.44tesla.com/dictionary/cat1021.htm
, but to run the network you need the Amp to be bi-directional (like the
first example.)

This one maybe close to what you need
http://www.multicap.be/uk/DM-AMP_BTB.shtml
(the big one with ribs on the picture), it may not be 10Wt, it may be ...
4Wt, by looking at it. I could not open their PDF though - gives me error.
Write them. It is in China, they may be 'pushing the boundaries'.

BTW, if you find out how powerful this Amp is, please let me know too.

Any fool can write a book that includes the words "RMS power". I've done it myself.

I have known since age 15 how to calculate the average power or an arbitrary AC waveform: "Take the root-mean-square averages of the voltage and current first, and then multiply those results together. Doing it the other way around gives the wrong answer, stupid boy!"

My particular mistake was to try to use "RMS power" as a shorthand label. I naively assumed that everybody would understand that it was short for:

"This is power that has been calculated by a *correct* use of RMS averaging, which we all know means taking the RMS average of the voltage or current first, and obviously it does not mean taking the RMS average of the power, because that would *not* be correct, and now that we've wasted half a paragraph on this point, and completely derailed the original train of thought, which was mostly about something else, I'd rather like to get back to our main topic."

Just writing "RMS power" seemed so much more appealing...

BIG mistake! It fell right into the gap between people who don't know how to calculate power correctly; and people who do know, but were all too eager to assume they'd found a fault.

I learned from that mistake... but the mistake itself is immortalised 6000 times over, in cold type.

3225. Tandem Match

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-10-20 10:08:59 UTC
From: Paul <g3zcuREMOVE@hotmail.com>
Message-ID: <cl5dd9qbq1@news6.svr.pol.co.uk>
Source record: 22509

I'm putting together the bits to build the tandem match from the 2001 ARRL Handbook. I do not have the original QST articles, but Googling has revealed that some builders have had a few problems, particularly those using the FAR Circuits PCB.

There's one thing I don't understand about the schematic and that just looks plain wrong. If both W2 and W3 jumpers are present, the 5.6k resistor is shorted out, thereby connecting the -2.5V and V- rails together. Surely this can't be right, or am I missing something?

Regards,

Paul G3ZCU

Not sure of the frequency that Primestar used, but the DirecTV dishes work well at 10 GHz. We remove all the electronics from the feedhorn (LNA, LNB, whatever) and bore out the waveguide to 0.75 inch and mount an SMA connector on the side with a probe sticking in horizontally (for horizontal polarization). We then usually put a solid metal plug into the rear of the waveguide and make it adjustable in and out to maximize gain/matching.

It is rather! I wonder how much the internal components cost?? The
site seems a bit short on technical info on these amps. What do they
mean by "bi-directional"? If they're talking about some sort of RX
preamp feature built in, it ain't gonna be 10W surely! :-)

Paul,

I've been following the thread still. Let me go back to the original question for a moment. So is the 4W maximum power of a CB radio is actually average power, not RMS, right? If it is modulated at 100% with a sine wave, what wil the PEP be? Is 16W the correct answer?

Chris
"Roy Lewallen" <w7el@eznec.com> wrote in message
news:10nb937ju41nee6@corp.supernews.com...
| Paul, I apologize. My browser showed only the first of the two pages,
| and I didn't realize that the second was there. While looking for the
| quotation I found that the second page was simply scrolled off screen.
|
| Yes, there is one thing (on that second page) I do disagree with the
| author on, that the equivalent power, the product of Vrms and Irms, is
| "RMS" power. I did a brief web search to find out who the author was so
| I could contact him about that, and discovered that it's Joe Carr.
| Unfortunately, he died a short time ago.
|
| Maybe my suggestion about looking in non-mathematical texts for an
| explanation wasn't such a good idea. It appears that some of the authors
| of those texts don't fully understand the math either. I'll have to say
| that you certainly have provided some evidence as to how widespread the
| misconception is. Next time I'm downtown at Powell's Technical
| Bookstore, I'll leaf through a few volumes oriented toward technicians
| and see just how bad it is. All I have on my bookshelf in the way of
| basic circuit analysis texts is two (Pearson and Maler, and Van
| Valkenburg) which are intended for beginning engineering students, and
| they of course both have it right. A popular elementary physics text
| which I have, Weidner & Sells, _Elementary Classical Physics_, Vol. 2,
| succinctly summarizes (p. 913): "Thus, the average rate at which thermal
| energy is dissipated in the resistor is the product of the rms voltage
| across it and the rms current through it." This follows immediately
| below an equation showing the calculation of pav from the classical
| definition of average which I posted some time ago.
|
| In response to the question about Vrms, Irms, and equivalent power, I
| said that when Vrms = 100 volts and Irms = 1 amp, Pavg = 100 watts and
| Prms is about 122.5 watts. I haven't had any previous occasion to
| calculate RMS power, so I might have made a mistake. According to my
| calculation, for sinusoidal voltage and current, the RMS power equals
| the average power (which is Vrms X Irms when the load is resistive)
| times the square root of 1.5. Surely some of the readers of this group
| can handle the calculus involved in the calculation -- it's at the level

| taught to freshman engineering students, and now often taught in high
| school. The calculation isn't hard, but it's a little tedious, so
| there's ample opportunity to make a mistake. I'd very much appreciate if
| one of you would take a few minutes and double-check my calculation. Or
| check it with Mathcad or a similar program. I'll be glad to get you
| started if you'll email me. And I'll be glad to post a correction if I
| did make a mistake.

I seriously doubt that : I've never seen tin plated RCA connectors.

However hearing the difference between gold plated and nickel plated RCA
connectors should be pretty easy for a well trained ear :
Just drop both connectors on a hard surface. Nickel plated and gold plated
shouldn't sound exactly the same.

AIUI the specified 4 Watts is the maximum*average* power allowed (in
the UK, anyway). When you modulate it 100% AM., it's still 4W average
power. If you fully modulate it with FM., it's *still* 4W average
power. But as you've seen here, for every assertion, there's a
contradiction. ;-)

It does look rather *large* for 10W, I guess. But is this due to the
frequency of operation? I mean, presumably efficiency drops off as one
goes up in frequency so maybe the PA is dissipating more heat than an
equivalent PA operating at, say, 430Mhz?

Presume you mean 400V.
Why not just buy one?

If you mean 4000V all you have to do is string some
caps in series. Use balancing resistors as your bleeder
and you are on the way.

Hi,

> There's one thing I don't understand about the schematic and that just looks
> plain wrong. If both W2 and W3 jumpers are present, the 5.6k resistor is
> shorted out, thereby connecting the -2.5V and V- rails together. Surely this
> can't be right, or am I missing something?

If operated from external supplies, all three links should be removed as opposed to battery operation where they must all be in place. You are right in that the 5.6k resistor is shorted-out but it is not needed in that configuration. Two links (W2 & W3) are required then to 'remove' the resistor and re-make the connection between the -ve power sensing detector and the bottom of the battery.

I didn't know the piece of equipment but looked it up out of curiosity.

Cheers - Joe

The average power of a 100% modulated 4 watt carrier is 6 watts, not 4. (If you want to look at it in the frequency domain, where the total power has to be the same as in the time domain, you've now got the original carrier plus two sidebands. The power in the two sidebands totals 2 watts.) And I'd give the answer to Chris' two questions as yes.

Pardon my saying so Roy, but I think you may be confusing the issue here. We all know that you understand this stuff backward and forward and most here have the highest regard for your expertise, including me. I also agree that you are totally correct in what you say.

The question was not what is the average power of a 100% modulated 4 watt carrier.
It was "is the 4 watt maximum power of a CB radio actually average power, not RMS right?"

He is trying to establish the meaning between so called (widely misused) RMS power and average. And he is also trying to figure out the relationship to pep.

Although you did acknowledge that he has the correct conclusion to his question, at the same time I think that you have injected some doubt in your answer. There are a lot of people that have trouble with some of the basics of this stuff. Throwing a little twist like that in often raises the confusion level with some. Again pardon me for comments.

Yikes... this thread is still running.

As I explained before there is a "common" usage which has unfortunately been adopted (and printed in the almighty and "always correct" text), which uses the words "RMS power" to actually mean the *average power*. An earlier poster explained that this term was also adoppted (still non mathetically correct) in audio circles to indicate a specific test.

This is not a correct usage because the term "RMS" means that it actually is a Root Mean Square value. [[square it, take the mean, then take the square root]] We just don't do this with power waveforms.

Sidebar:
I did extensive calculations of this type as a result of an article in QST earlier this year where it was proposed to use a VOM/DVM to measure line voltage and current(via a small series dropping resistor) to arrive at power draw of common ham equipment...OOPS!

I was, however, a bit puzzeled, Roy, why you went to the trouble of calculating the the RMS value of a power earlier. I suspect it was just to show that the value is indeed different (didn't check your math).

I will differ with Roy on one issue. The RMS value of voltage and current have, for many years, also been referred to as the "effective" values. This was to relate it to the DC heating effect (of resistance) we are all familiar with. It is, indeed just as "effective" as the same DC value, in producing power. This is another terminology issue I suspect some of you may wish to squabbling about, but is is not a 'what is correct technically' issue. It is cleat that probably all of you understand the math, but this is simply an nomenclature issue.

I feel sorry for Bill because he seems to understand the math:
>> understand about deriving the RMS power from the instantaneous power
>>in the same way that RMS voltage or current is derived,

...yet he said:
>>I just don't
>>accept the definition. It's been taught the other way all my life, even
>>though you say it's incorrect. I see your point, I just don't accept
>>it.

I don't understand when you say "I just don't accept the definition."
Does this mean that you do not accept thst "RMS Power" implies (to some of us) that you have done the Root Mean Square calculation on the power waveform? Which deffinition is giving you grief?

I am not not trying to prolong the pain (or this thread), it is just that I was born with a bone in my head that makes it hard for me to give up explaining some basic concept like this. (yep, it can be a curse) You're so close.

Hi Evan, This is not the point of contention. I think, at times, some posters get the wrong idea about the subject being discussed. I think all thoses in the discussion will agree with your statement. The issue is whether or not the words "RMS Power" are a _correct_ term to use for what some of us are saying should be called _Average Power_.

It is a discussion of terminology, not math or physics. a.k.a. what to _call_ this power, not what it _is_.

No pardon needed, Gary, and I appreciate your comments. I was only correcting what Paul said:

>>>AIUI the specified 4 Watts is the maximum*average* power allowed (in
>>>the UK, anyway). When you modulate it 100% AM., it's still 4W average
>>>power. . .

What's true is that the average *carrier* power is still 4 watts. But that's not what the posting said.

I think it's important to be careful with our terminology. The problem with being loose and free with it is that it causes us to keep having breakdowns in communication. It also ends up giving people a mistaken idea about how things work. A naive reader could easily take Paul's statement to mean that the average power of a 100% modulated 4 watt carrier is 4 watts -- that's what he said, after all (even though it might not be what he meant). The lengthy discussion about "RMS power" illustrates just how deeply rooted a misconception can get, simply from being careless with terminology.

If anyone considers this to be just nit-picking, that's ok. If you already understand it, just ignore my postings. But I hope it does serve a positive purpose for some readers.

And I'm guilty, too! I should have said that the average power of a 100% amplitude modulated 4 watt carrier is 6 watts *if the modulation is a sine wave*. When modulated by voice, the average power over any given interval can vary a great deal. That's why PEP is a more useful measurement of the modulated signal. As Ian humbly pointed out, it's really easy to be careless with terminology, and we all make mistakes. But I think we should keep trying to do better.

Paul -

The old PrimeStar 1 meter dish is very popular for S-band (2.4 GHz)
conversions - for satellite usage or 802.11 (WiFi) usage. They have also
been used successfully by amateur microwave users.

The DirecTV, old Primestar and Dish satellite services are above the 10 GHz
amateur allocation (usually spread between 11 - 13 GHz). Here is the 10 GHz
page:
http://www.qsl.net/n1bwt/

Bob, W0LMD has a very good web page for usage of the dish, positioning,
construction of feeds, etc..
http://www.ultimatecharger.com/dish.html

For S-band, you can build a helix or patch feed.
Commercial feeds are available from SSB Electronics (PA)
http://www.ssbusa.com/ham.html

Jim Miller, G3RUH Patch feed
http://www.jrmiller.demon.co.uk/products/patch.html

Yes, that was the only reason. As I mentioned, I'd never before had the occasion to calculate the RMS value of a power waveform -- it's simply not useful for anything. Except to illustrate that it's different from the very useful value of average power.

I don't have any disagreement with this. I just have to keep cautioning people not to extrapolate it to power. That is, just because the RMS value of voltage or current is an "effective" or DC equivalent value, don't think it implies that the RMS value of power must be its "effective" or DC equivalent value. It's not.

I have some ideas, but that's all. I hope someone with more recent direct experience with AM broadcasting than mine who really knows the answer will comment.

I will go out on a limb and speculate that the carrier isn't being reduced during modulation. If it were, simple envelope detectors would produce serious distortion. And if the carrier isn't being reduced, then the power has to be greater when modulation is present. But let's see if an expert will comment -- if I'm wrong I'll gladly eat my words.

Paul, why don't you simply say -

Total power = Carrier power + Power in the two sidebands.

When no sidebands, just the carrier power.

Not exactly a formal datasheet, but see the following URL for an article published in QST in Oct. 1974 that summarizes the then new 6MJ6 characteristics:

http://www.thermionic.org/sw6mj6.jpg

It provides info on input and output C, transconductance, max voltages, currents, dissipation etc....

Top post...

Well, friends, rather than speculate as we most certainly love to do, I just got off the phone with John, the KFI AM Engineer. (11:15am CDT Oct 21)

He said that althought that meter is a pretty standard toroid type power sampler (very like the common ham units, but it has no reflected output), it is not designed to read PEP, but couldn't say what they did in the design. He went on to speculate that the meter ballistics(how fast the meter responds to changes) may be a factor. He also said that due to the level of compression used, you won't see much dynamic range (variation of power with modulation level changes) He said that "it *does* vary if you look closely."
He advised that you *should have* looked at the final current meter. It *does* vary widely.

He also said that Harris is doing "some pretty interesting things in that transmitter." He described the transmitter as a "50kw D to A converter" with hot redundancy (extra amps on line) and if one of those smaller amps dies, you can see a "notch" in the output waveform, but that it doesn't cause any high frequency sidebands--due in part to the filtering effect of the antenna bandwidth, but he couldn't elaborate if this was the only bandwidth limiting factor preventing splatter from said notches. Thinking about it I wonder if "notch" was not the best word, but that "flat spot" might be mbtter...but then, I didn't think to ask...Oh well.

So there ya go...

One comment I feel compelled to make here. It is all too common for us to ASSUME that EVERY measurement made is absolutely 100% correct. I see Engineers do this all the time (and though 99.99% of the time this probably is right, there are those times when some corrupting factor gives a strange reading and the experienced Engineer is the one who figures out that something is amiss IN THE SHORTEST TIME-- cuz' we all get confused by strange observations). It is sort of a "It says so on the HP digital meter, so it has to be 100%" assumption. Easy trap to fall into. Meter says "power, therefore it must be reading MY interpretation of power."

Heep the faith AND keep asking...

>
>Ideas?

I'll take a stab at this. It is probably because of how the power is
being measured. An actual sample of output power is rarely used for
monitoring. They may have just a simple rf voltmeter measuring the
antenna line voltage, calibrated in watts. Many watt meters work in
this fashion.

When the carrier is modulated, the composite signal, carrier and side
band voltage swings up to twice the voltage and down to zero volts
with 100% positive and negative modulation. So the average voltage is

the voltage that the carrier produces itself. The meter can't follow the swings fast enough so it stays at the average which is equal to the carrier. The plate current meter is in the same situation. It stands still also with modulation for the same reason even though the plate voltage may swing between 2 times and zero.

If the modulation is not symmetrical, positive peaks greater than negative peaks, then you will see a slight upward kick with modulation as the average is no longer equal to the carrier voltage.

An antenna current meter on the other hand will show a definite upward kick with modulation. The current meter is usually the thermal couple type of meter that actually requires power for it to operate. Heating of a resistor in it is what makes it work. Heating that thermal couple requires power. Since power output only increases with modulation, it never goes below carrier level, the antenna ammeter sees an average power increase with modulation.

Hi Paul,

Vague memory but afair it is a UHF (lower UHF) power transistor, maybe 20 watts or so, 24V or 28V (not a 12V type). Could be ok for the 70cm ham band but that might already be a stretch, probably better for 2m.

Amps with devices like these didn't have a whole lot of gain when used at their upper frequency limits, certainly less than 10dB so you'd need something of about a quarter of the power you want as output to drive it.

Again, this is from memory so I am not 100% sure. My hunch is that you probably can buy 12V versions in a similar power range for little money these days.

Regards, Joerg

It's a UHF NPN power transistor. At 400 MHz, with VCC=28 V, and PO= 10W,
the gain is 8.2 db (min). Maximum collector current is 1.25 amp, and max
dissipation is 20 W @ 25C derated .114 W/C. Claimed collector efficiency is
60%. Moto must have second sourced this; it is in their 1991 RF book.

hello everybody,

For many years it's a common practice to shortcut the unused part of inductances in PA, Pi filters, etc, following the selected taps on the coil. We can consider that the shorted turns are in fact the shorted secondary of a transformer coupled to the primary made by the "hot turns". Consequently this would dissipate power and reduce the Q. Is this right or not ? Or told another way: is there any inconvenience in not shorting the unused turns ?

Thank you in advance for your explanations and experience.

73 de ON5MJ - Jacques.

This is true.

Consider a classic plate modulated Class C AM transmitter running 200
watts input. It requires 100 watts of audio for modulation. Assume it
has plate efficiency of 75%.

With no input to the modulator, the transmitter produces 150 watts of
RF from the 200 watts input. With sine-wave audio modulation, the
input rises to 300 watts (200 watts DC plus 100 watts audio) and the
total RF output rises to 225 watts. That's not a lot - only 75 watts
more (75% of 100).

Not the issue.

Both an RF voltmeter and a thermocouple ammeter require some power to
work. If the antenna is a linear load, the voltage and current must
retain a linear relationship, so that increasing one increases the
other.

IOW, voltmeter vs. ammeter makes no difference. Sorry.

The reason the power meter didn't move was probably due to averaging.
The measeurement system probably averages the power over several
seconds, rather than trying to follow the audio. If they had
transmitted just an unmodulated carrier for a long-enough time, you'd
see the power output drop. But BC stations don't do that intentionally
- "dead air" is a real no-no.

Well, I just tried it.

I set the carrier level out at 20 watts. Modulated the transmitter with a 1000 hz tone up to 100% modulation as seen on the scope monitoring the output of the transmitter. Using a drake w4 watt meter (same as a bird) the watt meter held steady at 20 watts. It read the same at full 100% modulation as it did with no modulation, just the carrier. No ALC involved here either.
Watching the scope the rf output voltage did double with 100% modulation as would be expected.

Now had I put a thermocouple rf ammeter in the coax line I would have seen an increase in the line current with modulation.

What did I do wrong?

Thank you Bill for your reply to my question.

Before posting this question my thinking was the following one: the loss could not be that low because many authors have written that antenna tuners have sometimes a huge amount of loss in their inductances. Of course, as you told, if the shorted part of the coil is not tightly coupled to the unshorted one, the problem is unrelevant. But how to estimate the degree of coupling for two close coils in line ?

Can also someone tell me what is the true purpose of this shorting and what could happen if the unused part of the coil is left unshorted ? Maybe is it done this way to avoid developping RF high voltage at the end of the unused part of the coil specially when the useful part of the coil is small.

I also will question a friend who is an expert in Pspice for simulating this problem.

Thank you for your advise.

> resonators, though.

Right... the reason I started down the 'coupled resonator' path was due to the fact that -- for bandpass filters -- the component values at high frequencies tend to be much more realizable than with the 'tradition' L->LC, C->CL structure.

In any case, I've found a paper that addresses the 'unreasonably small component value' problem -- it interleaves a low-pass filter with the band-stop filter, and then applies some transformations to get back to a 'reasonable' looking topology. The extra degree of freedom provides a lot of flexibility in obtaining 'big' component values (at the expense of having more components involved, of course).

Thanks for the help. I have played with Elsie, and it's a pretty nice program (even if it does insist on properly scaling its displays only when its window is maximized! :-)).

This (alone) doesn't work if you want a 2% bandwidth filter at 500MHz built using lumped L's and C's with finite Q's. Try it. :-)

I suspect that if one leaves the ends open one either has a problem with nasty resonances or one has a problem with too-high RF voltages.

The coupling isn't terribly tight, and the coil should be fairly efficient, so you may not lose that much (but checking it would be a good idea).

That tube must be as rare as hen's teeth. RCA stopped making
receiving tubes in 1975 or 1976 IIRC, and that was published in late
1974. So the tube was only made for 1 or 2 years at the most.
You'll NEVER see one in the flesh!

The explanations make sense to me.

The average *voltage* of an amplitude modulated signal equals the carrier voltage, provided that the modulation has no DC offset (that is, its average value is zero). This would be true for any waveform, provided that it's AC coupled and it's not DC level shifted, clipped, or otherwise distorted after the AC coupling. (It wouldn't be true of a classically overmodulated carrier, for example.) The average of an AC coupled waveform is always zero, if averaged over a time period that's long compared to the time constant of the coupling network.

So a power meter that's really reading the voltage should stay at the carrier level, provided that its time constant is comparable to or longer than the time constant of the AC coupling of the modulation signal. I'd expect this to be the case for a typical meter and typical audio modulation.

Even if you're monitoring the true power level, the average typically wouldn't get much greater than the carrier if you were modulating it with a normal voice. Compression would tend to raise the average some, though.

As I understand the Bird wattmeter, it basically takes current and voltage samples and adds them (rather than vectorially multiplying them, as a true power detector would have to do). What this would do to its response to average power I'm not sure, but I wouldn't expect it to give an accurate indication of either the carrier power or total power of a modulated signal.

We're confronted all the time with measurements that seem to contradict established theory. Some people regretfully are quick to embrace these as evidence that established theory is wrong. It does take some effort and knowledge to dig a bit to find out why there's a disagreement. But with a miniscule frequency of exceptions, the digging always reveals that we're not measuring what we think we are, we're using the wrong theory, or we're applying it wrong.

The shorted turns are not like shorted turns on a power transformer,
where the coupling between windings is very high. Shorting the turns
does lower the inductance of the remaining turns slightly and lowers
the Q as a result, but it's usually a lot better than leaving them
open and risking developing a very high voltage on the open turns due
to self-resonance effects. The power lost in the coil should be a
small percentage of the total dissipated power.

Cheers,
Tom

I think it is pin for pin, and electrically compatible with the 6JS6C,
and was the preffered replacement to use in the Dentron GLA-1000.
If I remember correctly, the 6MJ6 has more plate dissapation, and is
just a bit more rugged overall than the 6JS6C.

S-meters are driven by the AGC voltage, which is usually derived from the peak voltage of the signal. The peak value of an AM signal does increase with modulation, so it wouldn't surprise me to see one kick up a little once in a while on voice peaks when listening to AM.

Of course, they always kick upwards when listening to SSB -- just about none of what I've written applies to that mode.

Try making a simple RF voltmeter consisting of a diode detector driving
a sensitive moving coil meter (say 100microamp fsd) or a multimeter
reading volts. If the RF source doesn't already have a DC path to ground
(ie it is AC coupled), you will also need to add a shunt resistor or RF
choke. Make the resistor as low as possible without killing the RF too
much.

Apply sufficient RF to give (say) a half-scale reading. Now modulate the
signal with audio (to 100% if possible). The meter reading will stay the
same. Now add a fairly large capacitor across the meter (say 1uF). The
reading will increase. If the RF source impedance is low compared with
the resistance of the meter, the capacitor will discharge very little
when the diode is 'off', and the cap will charge up to the peak voltage.
With a good modulation waveform, 100% mod will double the reading.
(Note: Any capacitor value between 'far too small' and 'more than
enough' will give a reading somewhere between.

I did this about 30 years ago to add a simple mod depth indicator to and
old signal generator which already had an RF level meter.

Anyway, all this talk about power and PA efficiency tends to complicate
the explanation. Just think of the spectrum of the signal.
No mod = 0dB reference = the carrier.
Add mod. Sidebands appear each side of the carrier. The carrier level
stays at 0dB.
Set mod at 100%. Each sideband should be 6dB below the carrier level.

Total power = 0dB + -6dB + -6dB = 1 + 1/4 + 1/4 = 1.5
(Note: This is regardless how the modulation was applied).
Peak power can be got from the voltage waveform. The peak RF voltage
doubles with 100% mod. The peak power is proportional to the square of
the voltage, so it quadruples.

So, to sum up... for AM:
100% mod, power increases x1.5 wrt 0% mod.
100% mod, peak power is x4 wrt carrier.

Ian.

I think that you misunderstand what is being said.

Ham Radio is not a "hobby"; that is a description of
CB Radio.

Ham Radio is a technical pursuit for those suitably qualified - and
the M3/CB Fools' Licensee is not so qualified - he is specifically
forbidden to build his own gear from scratch and is therefore
not classifiable as a Ham by any stretch of the imagination.

You seem to be confusing a genuine concern that standards be
maintained with undesirable emotional attitudes that you yourself
project.

I append a short article to assist you to disambiguate the Ham from
the CBer.

------ooooo-----

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a

variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

Hi,

I'm keying my rig on RTTY via COM-1 of the computer but on start-up none of the standard software packages can find a COM port to use. If I go into 'Device Manager' though, delete a port and then re-install it, everything works fine until next time. This I guess means that the ports are not being initialised.

Has anyone come across this and is there a simple fix? I have already asked this question in the appropriate OS group (Windows XP Home) but to no avail.

Cheers - Joe, G3LLV

Do you have a PDA ? If so your may be running a com port Hot Sync
software on start up. I just installed some software for a Fluke
Scopemeter and ran into the very similar issue. The software
complained COM 1 was in use.

also possible in the system bios the com port is not enabled.

There have been some issues with Windows XP and how it allows for com
port control, you might do some google searches on that.

XP won't let you use the ports, some security issue. "
Being a very secure operating system, Windows NT
assigns some privileges and restrictions to different types of
programs running on it.It classifies all the programs in to two
categories , User mode and Kernel mode ie; running in ring3 and ring0
modes. user mode programs are running in ring3 mode and Kernel mode
programs are running in ring0 mode. The programs you generally write
falls in the user mode category. The user mode programs are restricted
to use certain instructions like IN, OUT etc.. Whenever the operating
system find that a user mode program is trying to execute such
instructions , the operating system stops execution of those programs
and will display an error message." from

<< Any suggestions? Thinking in terms of maybe 10W out / 200mW in or thereabouts. >>

Paul-

Kenwood may have made a 2400 MHz version of the TM-742, except it was equipped with only the one band module. I recall seeing a photo on a web site, but have not been able to find any additional information, so it may have only been a proposed product that was never produced.

If such a rig was actually produced, then you should be able to obtain one of the 2400 MHz amplifier modules as a replacement part.

Last year I replaced the Two Meter "SAV17" Fifty Watt module in my TM-742. It was obtained from RF Parts Company, http://www.rfparts.com/. Their catalog lists other similar modules for other frequency ranges, but none listed in their catalog are higher than 1300 MHz.

Four companies were mentioned as producing such modules, so researching their web sites might turn up what you are looking for. They are Motorola, Mitsubishi Electric, Philips and Toshiba.

I fired up my old 486 PC and tested a Radware DSP100 transceiver.

The DSP100 was an early attempt at a transceiver with a digital IF and modulation/demodulation
stages. It was a direct conversion transceiver.,built on a plugin ISA board, with a PLL/DDS synthesizer that
drove a Quadrature Mixer. Te two outputs of the quadrature mixer fed the left and right channels of the computer sound card
which did the filtering and demodulation/modulation.

It was produced by Comer Communications in the 1980's. The hardware and software was developed by two brothers, Alan and Brian Comer.

The sensitivity was fair and the software I have has some bugs, but it was a gallant attempt at the first
generation of "software defined receiver".

Does anyone have one or know what happened to Comer communications or have any experiences with the DSP100?
I have software versions 1.19 through 1.22. Does anyone have any later versions?

I have what appears to be an RF final module probabally from a commercial two-way mobile. Brown fins, UHF output connector with a small coax cable for the input. On the other end is a three conductor Molex type connector that has three wires on it but they don't connecto to the module. There a 5-conductor ribbon cable connected to various parts of the RF module. A couple of the wires are connected to temperature sensors on the heat sink and RF brick.

I am trying to figure out what the RF brick is. The numbers on the brick are:
185
3727966-1
144

The brick is blue and has no other symbols or markings. The RF module itself has no markings.

Anyone have any information on what the brick may be rated for?

Go directly to the Eimac website. They have added a whole line of newer version tubes using the 'Y' identification for the series. Many are similar to the older tetrodes, and many have weird shapes, and sockets.

Actually the TRW facility at Lawndale was purchased outright by
Motorola sometime between 1987 and 1990. The PT9703 was never
available from both mfrs simultaneously, so it was always
single-sourced.

One way to do this: use standard coil formulas to find the inductance of the whole coil, and of the part of the coil left unshorted, and of the part of the coil which is shorted out. From those three inductances, calcualte the coupling coefficient or the mutual inductance. Or...just measure it: you can measure the part of the coil which will be "in use" and see how much it changes as you short or open the other section.

Cheers,
Tom

Source record: 22497

Hi,

I've been trying to build my first superhet but I have been having problems.

What I have been doing is building seperate boards for each of the stages and debugging them seperately. I worked on the audio stages first.

My two AF boards are: 1) a low level X100 amplifier, and 2) an LM386 based power amplifier connected to speaker by RC network. Power supply is a 9V battery.

Each of these boards work fine seperately, I have tested them with an audio signal source and a scope. I used ground plane construction with each of these.

However, when I try to use capacitive or inductive coupling between the stages, I get the classic symptoms of motorboating... 10 to 45 hz out of the loudspeaker.

I have the ground planes of each respective board on a piece of aluminum foil, and both boards are connected in parallel to the 9V battery.

Advice, anyone?

Thanks,

The Eternal Squire

Hi,

Thanks for the suggestions everybody but I've already rounded up the usual suspects. I know that XP doesn't allow bit banging of the ports but it should be able to handle calls to them from applications in the usual way. If the COM port was not set up in the BIOS I wouldn't be able to start it via 'Device Manager', so this must be an issue between XP Home (SP2) and my machine.

Before I do something desperate like reloading the OS, I'm looking for a quick and dirty way to cycle the hardware. It only takes a few moments to do this from the keyboard but something like a macro would be nice.

Thanks again - Joe G3LLV

Some wild guesses <g>

- not enough decoupling on the 9v rail of the audio power amp (a
couple of hundred uF's as close as possible to the chip)

- speaker leads running too close to the inputs to the x100 amp

- try running the x100 board at less than 9v (anything from some
resistance and a decent electrolytic in the 9v line up to some
'proper' voltage regulation)

- some kind of an earth loop ? - if the board are connected by coax
try lifting the braid at one end of the cable

Hope these help ....?

You mean short the power leads of the 386 with 220uf? Also, the
X100 amplifier is an AMD instrumentation amp, should I short those
with a cap as well?

>
> - speaker leads running too close to the inputs to the x100 amp
>

The chain is in a single line, inputs on the left coming from
attenuated audio source, and about a foot to the right start the
leads to the speaker, thoseleads are only a few inches.

> - try running the x100 board at less than 9v (anything from some

I had read an article today on solving motorboating in tube audio
chains, and the B+ in each of the chains have different voltages. The
final stage had +220 V, the stage just before that +200 V, the stage
before that had +180 V, and resistors were used as the voltage drops.
I do not understand how that solved motorboating.

I mean, what I would do is place an 8V regular between the battery
and my X100 stage, and run the final stage off the 9V battery itself.
But can you tell me why this should work?

> - some kind of an earth loop ? - if the board are connected by coax

You mean leave the coax floating at one end? Wouldn't that disable
common-mode signal rejection?

Certainly you'd do well to get some capacitance across the 386.
The AMD amp is less critical - but you might like to put something a
bit smaller there as well. Can you put the circuits of the two modules
up on the web somewhere ?

I'm guessing (!) that your problems could be caused this way....

The power amp will pull a reasonably heavy current from the 9v battery
on audio peaks. This will result in the 9v 'dipping'. If the x100 amp
stage isn't decoupled itself then it may see the drop in the 9v rail
as a signal, which it will try to amplify. If it succeeds in doing
this then the power amp will pull a reasonably heavy current ... and
so it goes on. This could be the cuase of your oscillation..?
A big decoupling cap at the power amp will help to keep the 9v rail
constant, and mght cure the problem.

Mike -

Projects like this appear regularly in the amateur literature.

Chris Cieslak, AA9HD had a November 1997 QST article, "A simple
microphone/TNC/SSTV Switch" (Adobe Acrobat available to members from ARRL
web site)

The article references a Radio Shack multi-pole switch (275-1386A) -- which
may no longer be available. An old manual serial or parallel connector
switch can be salvaged (tons of this stuff in junk yards allover country)
for the manual (multi-pole) radio switch.

> for circuit simulation?
[clip]

The simulators basically offer 2 types of direct analysis ...
An "AC" analysis and a "Transient" analysis. Their answers come via
different maths methods.
Basically the much less useful 'AC' analysis examines all the wire
connection points 'nodes' in the circuit diagram and enters the found
components in 2 matrices. Each (square) matrix is sized to hold node^2
elements. One is for 'real' components, the other for quadrature components.
All non linear components in the circuit must first be simplified/replaced
by linear equivalants (messy). Matrices are filled in a manner similar to
kirchoffs loops anaysis. Reactive components entering the imaginary matrix.
Ie lots of real/imag simultaneous equations need solving which is of course
why the computer is handy.
After they are filled the matrices are mathematically inverted to give a
complete set of solved phase and ac voltage data for all the node points in
the circuit. Nice for filters useless for oscillators!.

The more useful transient analysis is similar to as you mention (Babbage's
difference engine?) but based simply on the differentials V=L i/t and V=i/C
and uses near complete maths models for the semicons or other non linear
elements. Nodes examined in turn and time steps selected purely on the
basis of how fast the results are changing. time steps can be a problem as
too long and the final results get 'smeared out' hence phase lag artifacts
cause overall loop stability problems.
The TA is conceptually very simple and surprisingly easy and fun to
programme for set piece or well observed circuits but gets *really* spagetti
code messy if it is to work smoothly with any input circuit. Big problems
can turn up getting the results to converge or balance and much progging
effort is needed in this direction.

I'll certainly try your suggestions and let you know.

Side question: is there a way to design this problem out of
circuits?

For example, would it work if I started with 12V main supply
and placed a 9V regulator on each board? Or would I still get
the same current dipping problem?

One important point is to make sure that the microphone ground (not the cable screen) is treated as a separate 'live' wire throughout and not grounded in the switch only in the rigs. Failure to do this can result in hum loops.

Cheers - Joe

3328. Any microwavers used one of these?

Hi Guys,

I am looking to identify the PSU requirements and specification for a
set of Sanders Microwave oscillators. type:-

CLC 2-4 (2-4GHz)
CLC 4-7 (4-7GHz)
CLC 7-12 (7-12GHz)

They each come in a red velvet lined case and consist of a heavy grey
painted body (cavity)? with large aluminium calibration scale on the front.
Each has an OCTAL valve base type connector on the rear that looks as
though it is a power-in socket. But are these straight supplies or is
the PSU cleverer?
There is a removable threaded cover at one end and this reveals the base
of a B7G valve, (disc seal triode?) which must be at the bottom of the
cavity as there is a large micrometer drive at the opposite end.
I don't want to dismantle any further for fear of upsetting any calibration.
Has anyone any technical data on these beautiful instruments please?

Thanks...Dave

Hello,

During my time surfing the web I have found a number of useful amateur radio antenna links. I would like to share some of these with you to add to your bookmarks or favorite links. For the online calculators I've found that if you save them in Internet Explorer as a web archive .mht file you can use the calculator offline because it is an HTML file. I hope you find these links as useful as I have.

Jim

Actually, the point is that you are engaging in rank speculation with
no proof, and assuming that it is so because you want it to be so.
That's not a very smart thing to do is it?

My problem is that I have an Icom 706 MK-II, that won't power up.
When I push the power button I can hear a relay click in the radio,
and a thump in the speaker but that is it. I've checked the fuses
internal and external all are ok. Does anyone have any suggestions as
to a fix this problem.

Thanks in advance and 73's

Don't forget to check your supply. The 706 needs about 11 volts and if you have the backlight turned on, it draws significant current in receive. In my wife's car, on a cold day, I get this symptom if the engine isn't running. If you measure less than 12 volts at the power plug, and/or if your supply lines are a little light, I'd be suspicious of that.

3348. Inexpensive Network Analyzer, Noise Figure Meter, Spectrum Analyzers, HP8640B's, etc

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-10-27 23:05:57 UTC
From: Rob <rob@pythonemproject.com>
Message-ID: <fRVfd.326769$D%.72460@attbi_s51>
Source record: 22432

By inexpensive, I mean half the price you would pay on EBay. LOL

1. HP8640B- have 3 of them, will sell them as a package only, $300
All are beat up cosmetically. One works fine. One puts out RF,
but display only works on external input.
Last one has a few freq ranges that do not work. There are a few
people out there who have made a
hobby out of fixing these up or using them for parts, so even the
dead ones are valuable. 440khz to 550Mhz
+17 to -141 dBm, extremely well shielded, useful for MDS
measurments, two for IMD measurements.

2. Agilent HP8712ET Network Analyzer. See Agilent site for details,
look for discontinued models. Is a 75ohm unit
but works well in 50 ohm environment with min-loss pads provided.
$3000. You will never find a modern network
analyzer at this price. (unless its stolen)

3. Noise figure meter. HP8970A with new Micronetics noise head 5db
ENR. $2000. Cosmetically in fair condition.
Operationally good. Will throw in second unit in need of repair
for free.

4. Spectrum Analyzers. HP8558B and HP8559A. Selling both as package.
$1000. Work fine as far as I can tell, but
I am not familiar with using these old units. The 8558 had a
loose concentric level knob. I think I fixed it, but
someone with more knowledge needs to check it out to see if
everything is lined up right before tightening knobs.

All of these units are sold AS-IS, no warranty. Only local OR, WA sales
as these items are very heavy with fragile front
panels. I will ship none of them. Or get a buddy near Portland, OR to
check them out, pay via cashiers check, and ship them.

Basically selling my test bench as I'm moving into an apartment soon.

That looks like a good analysis. I've just put the finishing touches on a non-mathematical analysis which I hope will be helpful for folks who can't or don't want to wade through the math. It uses simple square waves to illustrate the concepts. The link is

http://eznec.com/Amateur/'RMS Power'.pdf

Comments and corrections are welcome, either posted here or emailed to me.

Both the Rosenbaum and Lewallen papers look very good and well written.

I would, however, Roy, make a more explicit statement that while RMS power can be calculated, is has no practical value for the normal considerations of power...and add a note indicating something like that:

"The phrase "RMS Power" has been used in some circles not as an exact use of the term RMS, but rather as an informal "standard" that actually means "average power under specific text conditions". (I refer to an earlier post telling of the single channel, steady state audio power amp measurement) This use of the term "RMS" was originally initiated to call attention to the specific test. Unfortunately, this use has caused some confusion in the use of this terminology and is some of the motivation for the paper."

Is there a place in modern technique for regeneration (Q-multiplication)?

Hi Alan,

>Is there a place in modern technique for regeneration (Q-multiplication)?
>
>
Last time I used it was, oh, about 30 years ago. It worked great and
spared me the expense of a crystal filter. Nowadays it is possible to
use some cheap mixer chip, filter with a crystal at a frequency where it
is low enough in cost and then mix back to where the signal needs to be.

Also, I believe the art of such fine analog schemes is to a large extent
lost. Younger engineers often wouldn't even know what you mean by that
question. Thinking back to my days back at the university, have we ever
been taught regen or Q-multiplication? Nope.

Regards, Joerg

Rarely, if ever. Gain and selectivity are cheap nowadays, and
regeneration trades them for stability.

So after trying to mimick tube amps via algorithms the next big thing
would be the emulation of a Q multiplier on a DSP :-)

Yes, there are some kits available to build, seen them somewhere on the net.
There is also quenched regen. which works better than just regeneration.
Regen has the best sensitivity, but poor selectivity
It was popular in the first radios 1910 to 1925, then the superhets came
in, with better stability, but cost more.

I am trying to see if I can use some surplus 1/2 inch hardline
"feeder" for my 2m ssb loops and 440 sat antenna.
So far I can use my ssb loops from 144 to 145.4 under 2 to 1 swr.
And again from 146.5 to 148 as well. Keeping the Resistance at about
50 Ohms. The antenna SWR is 1.7 to 1 without the hardline.

Anyone else using CATV hardline for above HF freq.

I guess that depends on the application. I don't know how true it is, but I believe I saw that some of the 433 MHz ISM band receivers use either regenerative or superregenerative detectors. They are tiny and have sensitivities better than -106 dBm.

There has been new work on superregens (September/October 2000). An article was published in QEX, a ham radio journal. The first file at http://www.arrl.org/tis/info/vhfproj.html is that article but it requires membership to get it. However, on the same Web page, I see another that appears to be available without membership. It is An Ultra-Simple VHF Receiver for 6 Meters .

You can probably contact the ARRL and buy a reprint of the first article. It is well worth it. The author, Charles Kitchin, says the gain in a superregen detector is about a million. He discusses his discovery of shaping the quenching waveform so that selectivity is not lost. And he says it is possible to receive FM and NBFM as well as AM. It is a very enlightening article.

I plan to build a superregen to play with. After I get one going, I think I will try to make it work at 450 MHz. Like some other posters here, I built my previous regen 40 years ago.

Cheers,
John

Hi John,
I built a few superregens about 40 years ago too!! They were on 288 MHz when Australian amateurs had the one metre band. Surprisingly good sensitivity for a one-valve receiver (6J6 usually) but of course they put out a fair bit of rubbish over a fair bit of the band. I often wonder if the quench frequency could be better controlled - perhaps an external injection oscillator or something like that. Anyway, best of luck with your 450 MHz.

Yes, if that is the optimal way to meet the requirement. However, I'd have
thought a DSP based solution would be more likely.

Sure. Chief tech in Lafayette, IN. has hardline all over his tower. He even uses CATV electronics. An LE or Bridger's return module works to say 50 MHz and the forward modules go beyond 1 GHz these days with roughly 25 dB gain and what? 55 dBmV or so output. The bitch is needing a coring tool for every size of P3, QR. MC^2, etc. and the damned pin connectors ain't cheap. IIRC, a line splitter or DC was $450 ($250?) 8 yrs ago. I figure a power inserter might be the same. I'd take used gear and rework or build the actual itty bitty passive circuit if needed. The power passing stuff is just peripheral to all that and won't need to be messed with, anyway.

The ARRL HDBK has a 75 to 50 ohm torroidal xfmr. Dipoles and such should match real well, leaving any other matching equip near the rig.

The modular design of CATV equip is outstanding for commo systems inside or out in the weather. It's just big gear because of the power passing capability.

Yes, course there is.
Needed a 300Hz bp filter for an I.F stage. too wide for a crystal, too
narrow for a tuned circuit. Ended up using a Twin-T with feedback to give Q
enhancement and flat response.

>Is there a place in modern technique for regeneration (Q-multiplication)?

Not exactly what you asked for, but you might be interested to know
that this is exactly what is going on in your inner ear... and it's
partly mechanical! The sensory cells in your cochlea sit on the
basilar membrane, which vibrates from the incoming sound.
The sound enters at one end of the cochlea, where the
basilar membrane is narrow, stiff, and has low mass. The
membrane becomes wider, more massive, and less stiff as
you go toward the apex of the cochlea. The incoming sound
generates a travelling wave on the membrane, with a peak
at a frequency-specific location.

But it wouldn't be very sharply tuned just from the mechanics.
As it turns out, there are 2 different kinds of sensory cells
on the basilar membrane: one row of Inner Hair Cells which
actually tranduce the sound into neural signals to the brain,
and 3 rows of Outer Hair Cells which are electromechanical
amplifiers. They change length according to the voltage
across them, and they also change the flow of current and
hence the voltage across themselves when this happens.
The net effect is that they form a regenerative amplifier
that provides a huge Q-multiplication for the mechanical
tuning of the basilar membrane, and it is this enhanced
vibration that excites the Inner Hair Cells to give enhanced
sensitivity to low sound levels. Without this effect we'd
lose about 60 dB of sensitivity at low sound levels.
(The effect saturates at higher levels.)

Just thought you'd like to know!

Selectivity at the upper decades of Mhz is cheap nowadays? Where do I buy one of these flea-market tuneable multi-ganged, several-octave HF-VHF preselectors?

I wasn't thinking of regenerative detectors. I was thinking of a tuneable front-end preselector which would emulate the Q characteristics of a crystal-lattice bandpass filter.

don't we have nowadays, high-power, low-noise FETs which are almost as good as the vacuum tubes made in the late 60's, early 70's.

Stability? RF stability is like aircraft stability.... if your design and implementation are excellent, it would be hard to get into an unstable area of operation.

Don't expect lattice characteristics. I used a Q multiplier at IF
frequencies quite a bit when I was young. You can "dial in" almost any
bandwidth you like but the 6-60dB shape factor was never even close to
what a four or six crystal filter could do. You get the characterics of
a single tuned LC circuit which has a selectable Q. No more, no less. Of
course, you could gang Q multipliers but that is going to be very
complicated when it comes to aligning them.

>don't we have nowadays, high-power, low-noise FETs which are almost as

From a noise point of view they are better. But if you ever had to go
up a slippery roof after a thunderstorm to replace the amp board because
the FET had blown you start to appreciate tubes.

The old Q multipliers were kind of fickle. But then again, so is a
Ferrari. Things could be automated but this technology enjoyed too short
of a life span for that to happen.

But the first wto ar not tunable. At least not without using sandpaper ;-)

Direct DSP would be prohibitively expensive at VHF. Probably you'd have
to assemble an array the size of a large pizza and call the power
company before turning it on.

Ham fest, build your own, can get more than 10:1 over frequency.

Can get to a xal selectivity at all. You can do an elecrically tuneable
with Pin diodes and Fets. but it is at least 10 to 100 times wider.

Thats the easy part. First, you have to run the signal through an ADC.
Doing an ADC that has very many bits is tricky at high frequencies. You
would end up with a combination ADC and spaceheater.

How about a large copper tube as a wave guide and a plunger driven by an
electric motor? You can get sharp peaks out of such things. The bad part
is you never get just one peak. Perhaps using two or more you can arrange
it so that only one peak lines up in both (all three).

12 or 14 bit, 80 MSPS ADCs are cheap and plentiful nowadays, and
consume a few hundred milliwatts.

>
>
>
>Umm. Er Don't you mean negative?

No I mean positive. Lets take the simplest example:

```
--------------------------------
! !
--- !
--- C1 !
R1 ! R2 ! \ !
---/\/\/\------+------/\/\/\/----+---! K >----- +----
! ! / E1
!
---
--- C2
!
GND
```

Feed this circuit into spice with

R1 = R2 = 1 Ohm
C1 = C2 = 1 Farad

Try the circuit with K= 0.5 1 2 and 2.7 2.8 and 2.9

See what happens to the 0.03Hz to 0.3Hz band as you raise the gain and
hence the positive feedback.

An engineer I know attempted a design like that and found that (A) 14 bits
isn't enough and (B) 50 MSPS (his case) isn't enough either. Unless you
put an analog filter infront of the ADC, a strong station dominates and
the performance just isn't there.

You need to oversample enough that the Nyqist of the sampling system is
well above the highest frequency you intend to receive. This way, a
simple fixed anti-alias filter can keep the UHF band out of the front end.

The ADC's nonlinearity tends to intermix the various signals. Unless
there are enough bits or you can assume something lucky about the "noise"
of the other stations, the intermix products end up in the pass band.

Well, sure, but it's probably not going to be a regenerative amp
stage.

No, he ended up doing an analog superhet. down to an IF he then digitized.
The circuit was working great on the day the project was cancelled. It
was great electronics attempting to implement something the physics said
wouldn't work. He knew the idea was daft but he needed the work and they
wouldn't listen to him.

I think its possible it might become popular technology again. The
advantage of high gain per cost is attractive, and it has other
benefits. Stability is the prime issue: it can be controlled by low
frequency quenching, which can of course be adaptive. The question now
is whether a simple scheme can be devised that ensures consistent
stability and gain with small quench control circuit cost. If solid
stability is achieved, the rf emission problem is eliminated at the
same time. If its achieved at minimal cost, it may be a winner.

I know I've seen it used in some modern receiver chips, but damned if
I can remember the details.

Although superhets were conceived early on, they were absurdly
expensive. For most of the 30s the reaction set was still the prime
configuration, superhets stayed in the luxury bracket for some while.
Anyone that built a superhet in 1925 had to be rich.

Why ?

If we are talking about amateur band systems only, using suitable
high-Q front end band pass filtering (helical or cavity resonators),
you can limit the bandwidth to a few hundred kHz (e.g. the SSB or
satellite band). Then you only need a sampling frequency of the order
of 1 MHz and undersample (decimate) it and process it at that sampling
frequency.

3387. Electronic tuning (high voltage varactors)

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-10-30 08:22:51 UTC
From: Joel Kolstad <JKolstad71HatesSpam@Yahoo.Com>
Message-ID: <0OadnVBqe7yd0h7cRVn-jA@comcast.com>
Source record: 22371

I'm looking for suggestions on how one might go about changing the effective capacitance of a resonant circuit (it's part of a filter) in order to change the center frequency. The tricky part is that there's ~30dBm (10Vpp) RF running around, so with standard varactor diodes the RF becomes 'the bias' and the tuning is destroyed. I'm told that there are 'high voltage' varactor diodes out there; does anyone have a recommended source?

This is at 500MHz and the nominal component values are ~3pF. If I could obtain a 2:1 tuning range, I'd be happy. I need perhaps 30 steps within that range (3-6pF), and (doing the calculations) each step changes the capacitance by little more than about 100fF to start with -- so I'm thinking that switching physical capacitors into and out of the circuit is out of the question here.

Thoughts?

Thanks in advance,
---Joel Kolstad

3388. Re: Electronic tuning (high voltage varactors)

Source record: 22372

You might consider putting varactors or switched capacitors across only part of the inductor, i.e., a tap. The voltage will be lower and the required capacitance higher.

You might also consider ways to change the inductance instead of the capacitance.

Q, temperature stability, repeatability, and perhaps other factors will play a big role in determining which way is best, or acceptable.

Perhaps not tuning range, but if there are strong unwanted signal, you
are going to get a lot of unwanted mixing products (this is basically
a varactor multiplier :-).

Is there a specific reason for runnig the filter at 50 ohms (as it
would appear from your figures). Why not design your filter for, say,
1-10 ohms and the voltage range would be reduced.

>I'm told that there are 'high voltage'
>varactor diodes out there; does anyone have a recommended source?

You might investigate any ordinary small signal signal diodes (such as
1N4148or SMD equivalents) with sufficient breakdown voltages and look
for their reverse voltage vs. capacitance curve.

>This is at 500MHz and the nominal component values are ~3pF. If I could
>obtain a 2:1 tuning range, I'd be happy.

That would require a 4:1 capacitance range.

>I need perhaps 30 steps within

If you can switch in (using swithing diodes or reed relays) fixed
capacitances as base capacitances, this should not be a problem.

Put a small (perhaps 5 pF) fixed capacitor in series with a big
(perhaps even 5..50 pF) varactor and you can generate a moderate
tuning range. Using some back to back configuration with anodes at
ground potential and varactor varacitors at the tuning voltage, you
can also reduce the IMD products.

I'll ask around about progress on this. When I worked in the hearing
research lab, some folks were trying to come up with an animal model
so that they could study various treatments. At the time, they didn't
have any animals that developed hydrops spontaneously, so they
had to go in surgically to plug things up and prevent normal fluid
flow. I'm not sure it they came to any insights with this approach,
but it seemed a long shot to me. That was maybe 15 years ago,
so they could have come a long way. I still attend weekly seminars
in my old department, so I'll ask around about this.

You probably already know this, but the conventional advice is
to cut salt intake. That basically means you prepare all your own
food from scratch, in light of the amount of salt that restaurants
and processed food contains. Tough job, but easy enough to
try out.

Hello
My problrms with IC706 MKII are endless!!
I connected by accident the 8V ouput in the rear of TRX
to the Ground from the PC sound card!!!
Now the TRX is QRT.
Now Icom 706 MK-II won't power up.
When I push the power button I can hear a relay click in the radio,
and a thump in the speaker but that is it. I've checked the fuses
internal and external all are ok. For those who are familiar with
ic706MKII internal,
I made the followings measurements at the PLL unit
where the Internal 8V rehulator is located:
At the output of IC3..... 8.1 V
At the base of Q51 ..... 3.1 V
At the collector of Q51 ..... 2.32V
At the emetter of Q51 ..... 2.31V
At the collector of Q45 ..... 13.8V
At the emetter of Q45 ..... 0V !!

Because the Q45 is not SMD,I replaced itwith new one
But the problem stil exist.
Does anyone have any suggestions as
to fix this problem.

73

This method tends to increase noise unless something clever is done in the
area of the sample and hold. The device that does the sampling, must be
fast so there are a lot of sqrt(Hz) included. The sampling will alias the
high frequency noise from the device down.

You are better off to mix down to a lower frequency using something that
acts multiplying sinewaves so that there are no high frequency components
to cause the mixing of high frequency components. You can make sample and
hold circuits that act this way but you need more than one to make it work
right.

Very true!

> Is there a specific reason for runnig the filter at 50 ohms (as it
> would appear from your figures). Why not design your filter for, say,
> 1-10 ohms and the voltage range would be reduced.

No, a lower impedance would be fine. Still, even at 1 ohm, 30dBm is 1.43Vpp so it's still far from 'small signal.' I do realize that going from 50 ohms -> 1 ohm would get me capacitors that were 50 times as large, but on the other hand the inductors would be 50 times as small!

> You might investigate any ordinary small signal signal diodes (such as
> 1N4148or SMD equivalents) with sufficient breakdown voltages and look

Thanks, will do.

>>This is at 500MHz and the nominal component values are ~3pF. If I could
>>obtain a 2:1 tuning range, I'd be happy.
>
> That would require a 4:1 capacitance range.

Sorry, that was poorly worded. A 2:1 capacitance range giving a 1.414:1 tuning range would be fine. (Large tuning ranges are even better. :-))

> If you can switch in (using swithing diodes or reed relays) fixed
> capacitances as base capacitances, this should not be a problem.

If you mean 'reasonable sized' (maybe 3.3pF on up) by 'base capacitors,' that's what I was planning on doing. Initially I was planning on using reed relays, but having looked at some Hittite switches, I'm now planning on using a HMC221.

For ~100fF, I was thinking the problem is that you can't reliably switch in something as small as 100fF in that it's pretty hard to build anything that small in a repeatable manner. I mean, you can't buy a 100fF capacitor as a chip cap -- you end up just using a pad of copper on the PCB above a ground plane, right? Is that feasible? Perhaps if I stuck 4 such 'capacitors' in series, each one would then be ~400fF. However, at that point I'd presumably have to use a field solver to figure out the true capacitance

since all those copper pads are going to be pretty close together to one another and have non-negligible coupling.

> Put a small (perhaps 5 pF) fixed capacitor in series with a big
> (perhaps even 5..50 pF) varactor and you can generate a moderate
> tuning range. Using some back to back configuration with anodes at
> ground potential and varactor varacitors at the tuning voltage, you
> can also reduce the IMD products.

I'm not quite following this (I don't know what a 'varactor varacitor is'?). Something like:

signal -- | | -- |<| -- gnd

Where | | is the 5pF capacitor and |<| is the varactor with anode facing 'left'? I'm not following how the 'back to back' configuration works.

Thanks a lot for the help; you've given me a great deal to think about!

<< Side question: is there a way to design this problem out of circuits? >>

E.S.-

I can't say for sure about your circuit, but motorboating in general happens when peak current in the output stage develops an AC voltage across the power supply impedance, that is amplified by an earlier stage.

Yes, a separate regulator should fix the problem, but seems like over-kill. If you look at existing designs, they usually feed the output stage directly from the power source, and feed each earlier stage via a series resistor with a parallel capacitor across the previous stage.

Values of the resistors and capacitors depend on how much voltage drop the earlier stage can tolerate, and the lowest frequency of operation (or motorboating).

I don't know anything about this radio, but flex is short for flexible
(bendable, can be bent). Typically these cables are thin plastic sheets
with printed circuit traces on them rather than wires.

If the cable has a burnt trace, you may be able to see it with your
eyes.

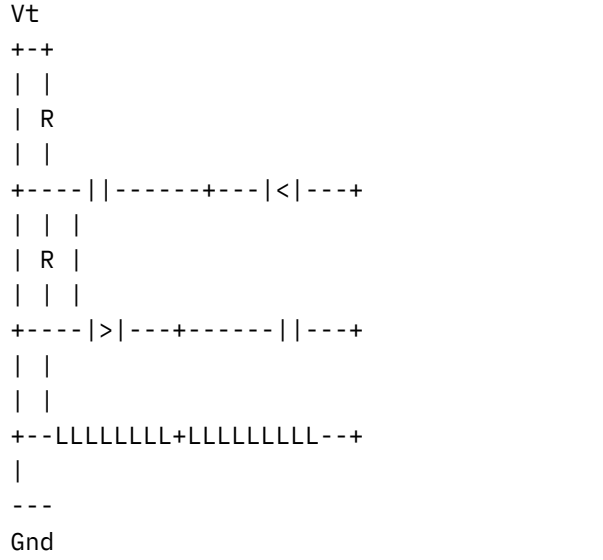
Something like this (fixed font):



The cent er of the inductance L is grounded to get ground reference
for the tuning voltage Vt. With a small series capacitance and a large
varactor capacitance, most of the RF voltage is over the fixed
capacitor. The anti-parallel structure should reduce the distortion.
You need to bring the tuning voltages Vt to the varactors through
separate resistors R (or through inductor resistor combinations).

My problems with IC706 MKII are endless!!

Its been harvest time in Morocco just now, surly you will be waiting for the cold wx for beating glands from the plants. Oh I wish I was in Morocco, sat out side a smoky cafe drinking apple tea, out side the casaba, sat with a big full bowled hookah pipe. Oh I wish.
(But then again my wireless is working)

Maybe there is a hidden fuse in the circuit, one that looks like a diode or something.

3402. 915 MHz receiver?

Maybe someone can answer this question, I understand that the reciever for the DirectTV box is around 1GHz, the 12GHz from the disk is down converted to this range so that the loss in the cable can be less.

I have seen a few of the receivers around the yard sales for 5 bucks or less. Complete systems for about 15 bucks.

I was considering getting one and see what I could do to make it usable at around 915MHz. I also understand that voltage is on the cable and this could be used to power a rf amp at the antenna end.

This reciever most likely has a wide bandwidth, which is good for some ATV work.

Has anyone here opened the receiver box up to see what under the hood?

Maybe a tech site with data on the reciever?

Thanks!

Paul

Chafik -

Yes, you damage the 8 VDC voltage supply - it can take only 10 mA and a dead short does destroy a number of internal components within the radio (you will need the schematic) and test components from that shorted output.

Icom Worldwide web site has the manual for this radio
http://www.icom.co.jp/world/support/index.htm

It may have to go to Icom service center for repair:

Spain Icom Spain S.L. 93-590-26-70 93-589-04-46 icom@icomspain.com

Egypt Egyptec Computers & Communication 02-2879585,

Just acquired a Small Wonder Labs "White Mountain 75" QRP SSB tranceiver. It works quite well as designed but would like to add a DDS VFO with LCD frequency readout and re-package it all mainly for PSK use. Looking for plans with PCB patterns and any hex code for a suitable DDS VFO, or alternatively a VCO stabilizer with freq readout. Googling turned up a few articles but not a package that I can build myself from scratch not a kit job. Any pointers greatly appreciated.

Nigel

FAR Circuits has the PC board for the circuit described by WB2V in QEX. This is pretty simple and works well, although the board quality from FAR Circuits leaves something to be desired. I think you can also get a reprint of the article from them. (http://www.farcircuits.net/vfo2.htm#2vfo).

Another approach is to build something up from the DDS Daughtercard from AmQRP. This little board deals with all the hard stuff, but you would need to sort out driving it yourself. (http://www.njqrp.org/dds/index.html). AmQRP's PIC-EL provides an LCD display and drive for the board and is well documented on their site. (http://www.amqrp.org/elmer160/board/index.html) However, the PIC-EL itself is no longer available (and more that what you need, anyway). But the schematics and code on the site could provide you with what you need to roll your own.

The DDS Daughtercard is a nice approach because it mostly handles the hard part. Most of the DDS chips are only in TSSOP or smaller. Making a PCB that fine is a little tough for most hobbyists. The Daughtercard has the DDS chip, the oscillator to drive it, a regulator, and a little amplifier to get the output up a tad. It plugs into a normal 0.1" header. The thing is really tiny so you have a lot of packaging options.

..

Does it have to be an LCD display? G3XJP has produced a very good design,
which can be found at Analog's website with the following URL:
http://tinyurl.com/65ggv

Foil patterns etc are available for this design at
http://tinyurl.com/3k568

It is a very satisfying build - hex code for the PIC is available either
from Peter Rhodes G3XJP, or if you join the Pic-a-star Yahoo group, from
there.

Best of luck

3408. Stripping thin flat Ribbon cable (like Kapton)

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-01 03:54:55 UTC
From: **THE-RFI-EMI-GUY** <rhyolite@nettally.com>
Message-ID: <cm4c1qaro2@news.utelfla.com>
Source record: 22392

I just had the "pleasant experience" of having a ribbon conductor break in some 1997 vintage ham equipment. It is a ~16 conductor ribbon cable ~1/2" wide which looks a lot like Kapton only it has white insulation, possibly epoxy. On one end the conductors are factory stripped and plug directly into a latching receptacle. The other end, where the breakage occurred was factory stripped and soldered to the surface of the circuit board. After much angst, heat and scraping I was able to strip the end of the conductor and resolder to the circuit board. I have to say, my job doesn't look too bad, but I had to start over once. It burns easily in a flame, but is hard to melt with soldering iron.

Can someone advise how this stuff is stripped in the factory without nicking the conductors? Can it be bought in factory made lengths as opposed to bulk?

> Can someone advise how this stuff is stripped in the factory without
> nicking the conductors?

It's a small machine that usually has a long V-shaped blade that comes down to slice into the insulation from both sides while the rest of the cable is held firmly by blocks. The cut is made, e.g., 1/4" back from the end of the cable, and merely pulling on the remaining cable is enough to free the long end.

At least that's the way the one I've used worked; it was semi-automatic (you had to manually position and pull the cable -- the slicing action was done from pneumatically powered pistons). There were numerous set screw adjustments to get the spacing of everything just right, but once it was set up, it tended to stay in alginment for a long time. I'm sure the thing costs thousands of dollars.

> Can it be bought in factory made lengths as opposed to bulk?

Yes, even DigiKey will sell you small quantities of pre-stripped cable at very reasonable prices (well, spendy compared to having your own machine around, but cheap compared to having to do it by hand).

Hello everybody:

thank you for all your suggestions, I have already repaired/adjusted the power supply, some switches and the optical encoder.

It seem the 100 KHz resolution filter does not work properly (83 KHz of error in bandwidth according to the internal calibration routine) and the 1st LO sometimes fails to lock at low frequencies...50KHz-200KHz.

Does anybody have any suggestions? I have all the manuals and trying to solve it.
Any place where I could get working modules or board extenders???

Thank you

> PSK use. Looking for plans with PCB patterns and any hex code for a
> suitable DDS VFO...

I have a follow-on for the Siggen project (i.e., Far Circuits board running my Siggen3a code)
or my PICELgen code running the PIC-EL. It is going to be released by AmQRP very soon.

My new DDS VFO (called IQ-VFO) has some significant advantages over the previous
DDS VFO. This one uses a more advanced DDS (the Analog Devices AD9854) which produces
two outputs (In-phase and Quadrature) on any frequency from 0 to 30 MHz. The two signals
provide endless modulation/demodulation possibilities.

Full kits will be available as well as the bare boards, etc. My source code for the two PIC
microcontrollers that control the IQ-VFO is also available so modifications are encouraged/expected.

You can see detals about the IQ-VFO on my web page: www.cbjohns.com/aa0zz

Also, a few days ago I opened up a YAHOO group (called DDS-VFO) to discuss DDS VFOs and
this IQ-VFO in particular. Please join us there.

Swan sold a lot of equipment and a lot of people were very satisified
with it. Yes they might drift a little but all the radios of that time
did. Swan was one of the first to make a transceiver if not the first.
Swan was a key player in our history so go knock Collins that should
have been right up at the top that also had numerous problems. Swan gave
the rest of us something to operate if the person wasn't a homebrew type
so rich.

Paul,
The "back to back" configuration I am familiar with is like this:

> + Control voltage
> |
> R
> |
> +----|>|-----+---|<|---+
> | |
> | |
> +--LLLLLLLL+LLLLLLLL--+

There could also be a series cap in this configuration--except a resistor or choke would be required on one of the varactors. (no different than the one to the control line)
I don't know the advantages of either config. as the RF cycle effects each diode the same way "on opposite half cycles" in either.

I also don't get this talk about the filter Z. Since you'd need to Z match in/out of the filter, it seems to me the varactor voltages will be the same for any Zin/out since this will be determined by how "tightly" they are coupled into the resonant circuit and not the Zin/Zout, no? The Z match will just change the Vin/out.

Most of the designs out there use PIC micro's. Nothing wrong with that,
the pics are very good micros. HOWEVER, I think you guys should
consider the AVR MEGA chips. A real jtag ice is available for $300 from
Atmel, or you can build your own jtag interface or buy a clone for under
$50. (Google for 'bootice'. Uses only two IC's some connectors,
some connectors, a few resistors and a Led or two.)
A "C" compilier, assembler, and debugger is available for a free
download, and all the tools will work under Windows or Linux! The
Avr Mega series are available in 40 pin dip or 44 pin surface mount
packages with 16k or 32k of flash program memory (10k to 100k program
cycles), 1-2k of static ram, and 512-1024k eeprom (100k to 1000k program
cycles). They make denser versions in 64pin surface mount packages that
have more io pins, and external memory bus (sram only) as well as 'tiny'
chips in 28 pin skinny dip (no jtag interface on these though).

The rich development tools (easier than a software simulator and C
programming instead of assembler) make the AVR worth considering.
I don't work for Atmel, but I am using the Avr Mega chips at work,
and they ARE easy to use. The cost may be a little higher than
the pics, but only slightly so. Check out www.avrfreaks.org

My 50 cents worth.

83 kHz of what? The self-calibration routine displays the *center*
frequency error of the filter, not its bandwidth. 83 kHz off-frequency
is not ideal but probably still OK.

What is the dB value (+/-) that the self-cal screen displays for this
filter? Does the routine complete without displaying any error
messages?

> and the

You might try the LO calibration procedure as described in service
volume 1. It doesn't take very long.

Source record: 22303

Hi,

Wonder if anyone can help.

Q1.

Fresh off of eBay, this SA is having terrible problems with input RF leaking straight through to the IF on the lowest RF range. I assume that the input mixer is shot (441-0671-03).

If I remove the LO feed to this mixer, the expected signal goes away, but the crud remains. I assume that the IF on the lowest RF range is close to one of the broadcast bands (TV or FM).

The mixer assy has two diodes which look like they should be easy to replace. Does anyone have a schematic for this assy or maybe just tell me what these devices are and some idea where I might get replacements.

Q2.

I feed in 144 Mhz and crank the SA centre frequency lower (130MHz) and the trace shifts left (I rather expected it to shift right). I assume that this could be connected with the busted mixer ?

Q3.

This one is defiantly operator error. The mid range 'B' has two scales 270 - 900 and 800 - 2000MHz. How do I switch between these two ranges (!)

Thanks in advance.

Mark.

You would need fixed capacitors on _both_ anodes and also resistors to
ground from both anodes to get the DC bias. The small series
capacitors are essential, since they take the most part of the RF
voltage. Of course, the series resistor will reduce the tuning range.

You could get away with the series capacitor and put multiple (maybe
10) varactors in series. Thus, the RF voltage across each varactor
would be low. You will need a high tuning voltage, perhaps 100 V.

The worst problem is how to get the DC voltage distributed over the
varactors. The simple solution would be to put resistors across each
varactor to form a voltage divider. Apart from possible thermal noise
problems (if weak signals are also involved), the nasty thing is the
resistors will have a parasitic capacitance across the ends of the
resistor. This capacitance is in parallel with the varactor, forming a
significant base capacitance. Also the losses (and hence Q) of these
parallel parasitic capacitances may degrade the total Q of the
resonant circuit. Putting multiple varactors in series also increase
the total inductance, which would not be so nice in this case, since
the inductance levels are already low.

However, if the parasitic capacitance/diode is much less than the
varactor minimum capacitance, quite large tuning ranges could be
obtained.

>I also don't get this talk about the filter Z. Since you'd need to Z match

>will just change the Vin/out.

Think about two resonant circuits coupled by a small capacitance at the top. Connect the signal from the input line to the first resonator using inductive coupling (transformer with untuned primary). By selecting the number of turns on the primary, you can get any impedance transformation ratio, so you can match the 50 ohm line to any low impedance resonator. On the output side on the other resonator, you can do the opposite with the other transformer and restore the impedance to 50 ohms for the output line.

To reduce the Z in a resonator, you will have to reduce both the inductive Xl and capacitive Xc reactance by reducing the inductance and increasing the capacitance (e.g. by multiple varactors).

Rhode wrote an article in QST a few years ago about running the HF varactor tuning front end at a lower impedance level to avoid the high RF voltages on the varactors.

In VHF/UHF reducing the inductance to enable larger capacitances and thus lower impedance and RF voltages is problematic, since the inductance is already extremely small.

In principle it should be possible to connect several "coils" in parallel (actual wire loops across the capacitor) and this is how many text books explain how the cavity resonators are formed by adding further and further wire loops surrounding the capacitor. However, I have never seen parallel "coils" in any practical circuit, apparently there are some parasitic capacitance problems.

However, I think that the OP should also study of making a shortened 1/4 (stripline or microstrip) resonator, with very wide resonators (and thus low impedance levels) and do the impedance transformation at the input and output coupling. If multiple stage filtering is needed, look for interdigital filters and again design for low resonator impedances to reduce the RF voltage across the tuning capacitors. These might be more practical for the intended frequencies than ordinary LC filters.

If the tuning speed is not very large, look for some mechanical tuning at the end of the stripline resonator, such as moving the grounding electrode closer to the resonator hot end by a piezoelectric crystal etc., thus increasing the capacitance.

Hi Paul,

Thanks again for the suggestions; I need to do a few simulations to see how viable some of the approaches are.

> However, I think that the OP should also study of making a shortened
> 1/4 (stripline or microstrip) resonator, with very wide resonators
> (and thus low impedance levels) and do the impedance transformation at
> the input and output coupling.

The problem with this approach is that I've yet to see a stripline/microstrip resonator design that -- by design -- doesn't have re-entrant modes well before covering a 16.7:1 range (30-500MHz, in my case). Otherwise I'd be all for it!

> If the tuning speed is not very large

It's not, 'some low number of seconds' to re-tune is fine.

I don't suppose anyone makes motorized piston trimmer caps? Sure would be nice...

Hi Paul,

Why both? It is the total series cap which is of concern. One cap
would simply be half the value of each of the two. 2 x 5pf = 1 x 2.5pf,
no?

>Of course, the series resistor will reduce the tuning range.

I don't see this. It would be just like the one shown. 100k or 1M. It
is for DC and is large enough to be neglegible at RF. (strays acknowledged)

I think there are many two diode configurations.
One option:
> >> + Control voltage
> >> |
> >> R
> >> 2.5pf |

I agree, Clearly a complex arrangement. However, is there really an
advantage to having low voltage if you now have so many contributors to the
problems...

> ... I also don't get this talk about the filter Z. Since you'd need to Z
match
> >in/out of the filter, it seems to me the varactor voltages will be the

> >will just change the Vin/out.
>
> [describes z matching in/out of a filter...]

That's my point. Once you select an inductor type, you have fixed a number of future decisions. The transformation can get you to wherever you need to be *IN* the resonator....see next
>
> To reduce the Z in a resonator, you will have to reduce both the
> inductive Xl and capacitive Xc reactance by reducing the inductance
> and increasing the capacitance (e.g. by multiple varactors).

So now the varactor must be _more_ of the overall capacitance to get the desired tuning range, no. If you want minimal side effects, then the varactors need to be just barely inthe circuit, so to speak, which means that they will have small voltages.
>
> Rhode wrote an article in QST a few years ago about running the HF
> varactor tuning front end at a lower impedance level to avoid the high
> RF voltages on the varactors.

Probably necessary reading, but I guess that I am trying to point out that this is one of those "no free lunch" situations. That a wide tuning range AND good IM, temp performance are each pulling the design in opposite directions? I mean:
Wide tuning - means -> varactors need to be a larger fraction of the total capacitance...
But this means that the non linearity and temp drift of the diode has more effect.
If you put series caps to reduce voltage, although you are reducing the effect of cap non linearity and temp drift because the diode is now "decoupled" from the tuned circuit, you are reducing the potential tuning range.

I have no significant comments on most of the rest...except...

> ...However, I
> have never seen parallel "coils" in any practical circuit, apparently
> there are some parasitic capacitance problems.

Side bar: My first "short wave" receiver did this.
Take one 50's tube AM radio. Parallel both the RF
and LO coils with outboard coils to get 75 Meter
phone band (it was mostly AM then). I think it was
in Popular Electronics or some such mag.
>
> However, I think that the OP should also study of making a shortened
> 1/4 (stripline or microstrip) resonator, with very wide resonators

Been there, done that (not varactor tuned, though). The needed direction.

> (and thus low impedance levels) and do the impedance transformation at

> look for interdigital filters

Sure, Interdigital or combline... 220, 221. Whatever it takes...

>
> If the tuning speed is not very large, look for some mechanical tuning
> at the end of the stripline resonator,

Something you should not reject is a "ranged" system. Tune a smaller
range with the varactors and switch in/out other caps for larger shifts.

Fine, fella...but the Siltronix 1011 was just the precursor to
"export" radios. Thinly disguised as a 10 meter rig, it was sold to
the CB market. Swan marketed it under the Siltronix name just so they
wouldnt be accused of pandering to illegal keyclown CB'ers. No way
were hams going to pay that price for a monoband radio, especially one
that didnt just "drift"...those junkpiles MIGRATED!

Yes, it is doable with one fixed capacitor, however, the voltages
across the stray capacitances would be different and their effect
would be harder to predict.

For a given total capacitance, putting more varactors in parallel means that the capacitance each varactor must produce is reduced, thus the tuning voltage must be increased, which is a good thing, since this improves the ratio between the tuning voltage and RF voltage. Dropping the impedance levels and hence increasing the capacitance required also means that even more varactors can be connected in parallel.

The OP clearly had something similar in mind, since he originally asked for a 2:1 tuning range, but now he is asking for the 30-500 MHz range. I do not think that such huge range can be handled by just switching base capacitors. With such large frequency range, it would make more sense, to build at least three completely independent filters, say 30-90 MHz, 90-270 MHz and 270-500 MHz, while each filter could switch in base capacitances. The two lower filters could be lumped LC filters, while the last range could be limited to less than one octave, so that strip line filters could be used.

I was thinking of two... 30-125MHz and 125-500MHz. I.e., each one tunes a range of about 4:1. Something like 3-5 base capacitors would provide the broad tuning, with varactors doing the fine tuning.

> The two lower filters could be
> lumped LC filters, while the last range could be limited to less than

The problem is that even though the 125-500MHz filter only needs to create a bandstop region somewhere in the 125-500MHz range, it must otherwise still pass the complete 30-500MHz range. As far as I can tell, this still eliminates all distributed-style filters from consideration.

Hi to all
I have a capacitor that is leaking a cruddy white substance. The only thing on it is as follows.
SPRAGUE +
183-1901-00
250 - 30 DC
D35672

6626

I listed the info just as it appears on the cap. I can see that it is an aluminum polerized cap. However, I need to find out the values so I can replace it.
Thanks to all that reply.

My guess would be 250 uF @30VDC
Dale W4OP

Yes, at the higher freqs, strays become significant, as I remarked.
...

... Let me ponder this... By golly, running several parallel varactors at
fifty volts does sound good, doesn't it. You are away from the high
non-linear region near zero. Never had that option, I guess.

I would agree with Dale. You can substitute with a high voltage rating (35 VDC or 50 VDC), if you can not find a capacitor with a 30 VDC. DO NOT go to a smaller voltage rating (25 VDC or 16 VDC), unless you are POSITIVE the capacitor "in circuit" will never reach this voltage (peak or otherwise).

He's just pissed cause he was out of the loop in the day and no one would
sell him one. Much like now. :-)

It cost him extra to find out they drift a bit..but he was able to
finally purchase one with the money that was supposed to feed his family.

That's why he's so bitter about 11 meters.

3434. Please Recommend Wireless Protocol and How-To/Tutorial

Newsgroup: rec.radio.amateur.homebrew

I am a student in an embedded systems design class. I am planning a project where I'll get two 8051-microcontroller-based development boards with 433 MHz FM transceivers to talk to each other. Each development board will be connected via RS-232 to a computer running terminal software. My initial goal is to be able to send some keystrokes back and forth between the two systems.

The real challenge of the project is in developing my own wireless protocol to handle packetization, start and stop codes, error detection and correction, line coding, and perhaps collision handling. I am looking for a good tutorial on how to go about such a task--i.e. what options are available and guidelines for implementing them. Something on the web or a book would both be good. I was wondering if you might be able to make a recommendation.

Additionally, if you would please recommend any existing protocols that would be sufficient for my application, this would be very helpful because: a) I can use the existing protocol as a reference when developing my own and b) If it turns out to be too difficult to develop my own, I can switch my goal to implementing the existing protocol.

I would be very grateful for any assistance that you might be able to provide. Thanks so much for your help.

Dude, do your own research :-)

I ordered these from www.futurlec.com:

http://www.futurlec.com/Radio.shtml

Good stuff for hobby projects.

S.

The two that amateurs use are x25 and tcpip. The ham radio implemetation of
x25 (ax25) is what is used in packet radio. It is well documented in all
communication layers. Tcpip is well documented in the internet rfc and other
docs, though I don't remember seeing any timing specs like are included in
x25.

Do a google search on "serial transfer protocol". You will get about
500,000 hits.

Initially look for the standard terminal communication protocol. That
already has some form of packetization, start and stop codes, error
detection and correction. It's relatively simple so you can expand from
there.

Didn't the supplier of the transceivers give you any application
guidelines?

Rufus

THE QUICKEST WAY TO MAKE EASY MONEY_NO SCAM" A while back, I was browsing these newsgroups, just like you are now, and came across an article similar to this that said you could make thousands of CASH within weeks with only an initial investment of $6.00 plus stamps! So I thought, "Yeah, right, this must be a scam!" But like most of us I was curious and kept reading. It said that if you send $1.00 to each of the 6 names and addresses listed in the article, you could make thousands in a very short period of time. You then place your own name and address at the bottom of the list at #6, and post the article to at least 300 newsgroups. (There are about 32,000 of them out there and that's quite a large market pool). No catch, that was it. Even though the investment was a measly $6, I had three questions that needed to be answered before I could get involved in this sort of thing. 1. IS THIS REALLY LEGAL? I called a lawyer first. The lawyer was a little sceptical that I would actually make any CASH but he said it WAS LEGAL if I wanted to try it. I told him it sounded a lot like a chain letter but the details of the system (SEE BELOW) actually made it a legitimate legal business. 2. IS OK WITH THE POST OFFICE OR IS IT MAIL FRAUD? I called them: 1_800_725_2161 and they confirmed THIS IS ABSOLUTELY LEGAL! (See 18, h sections1302 NS 1341 of Postal Lottery Laws). This clarifies the program of collecting names and addresses for a mailing list. 3. IS IT RIGHT? Well, everyone who sends me a buck has a good chance of getting A LOT of CASH ... a much better chance than buying a lottery ticket!!! So, having these questions answered, I invested EXACTLY six $1.00 bills and six 37 cent postage stamps ... and boy am I glad I did!!! Within 7 days, I started getting CASH in the mail! I was shocked! I figured it would end soon and didn't give it another thought. But the CASH continued coming in. In my first week I made between $20 to $30. By the end of the second week I had a made a total of $1,000.00. In the third week I had over $10,000.00 and it was still growing. This is now my fourth week and I have made a total of just over $42,000 and it's still coming in ..... It's certainly worth $6.00 and 6 stamps !!! Also, make sure you print a copy of this article NOW, so you can get the information off of it as you need it. I promise you that if you follow the directions exactly, that you will start making more CASH than you thought possible by doing something so easy! Suggestion: Read this entire message carefully! (print it out or download it.) Follow the simple directions and watch the CASH come in! It's easy. It's legal. And, your investment is only $6.00 (Plus postage)

IMPORTANT: This is not a rip off; it is not indecent; it is not illegal; and it is virtually no risk it really works!!!! If all of the following instructions are adhered to, you will receive extraordinary dividends. PLEASE NOTE: Please follow these directions EXACTLY, and $50,000 or more can be yours in 20 to 60 days. This program remains successful because of the honesty and integrity of the participants. Please continue its success by

carefully adhering to the instructions. You will now become part of the Mail Order business. In this business your product is not solid and tangible, it's a service. You are in the business of developing Mailing Lists. Many large corporations are happy to pay big bucks for quality lists. However, the CASH made from the mailing lists is secondary to the income which is made from people like you and me asking to be included in that list. Here are the 4 easy steps to success: STEP 1: Get 6 separate pieces of paper and write the following on each piece of paper "PLEASE PUT ME ON YOUR MAILING LIST." Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelope (to prevent thievery). Place one paper in each of the 6 envelopes and seal them. You should now have 6 sealed envelopes, each with a piece of paper stating the above phrase, your name and address, and a $1.00 bill. What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate service and you are paying for it! Like most of us I was a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the U.S. Post Office (1_800_725_2161) and they confirmed that it is indeed legal! Mail the 6 envelopes to the following addresses:

#1) Justin Carney 2802 Noble Fir Ct Woodbridge, VA 22192
#2) Anthony Pappion Sutherland Hall 811E-2 3725 Sutherland Dr. Pittsburg, PA 15213
#3) L. Lewis P.O. Box 203 Gambrills, MD 21054
#4) J.A. Goode 3955 S Algonquin Dr #70 Las Vegas, NV 89119
#5) Kenneth Murphy 139 Argyle St. Keyser, WV 26726
#6)Roy Broesky, 182C Chapel Drive, Steinbach, Manitoba, Canada R5G 2H7

STEP 2: Now take the #1 name off the list that you see above, move the other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number 6 on the list. STEP 3: Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 300 newsgroups. (I think there are close to 32,000 groups) All you need is 300, but remember, the more you post, the more CASH you make! This is perfectly legal! If you have any doubts, refer to 18 Sec. 1302 & 1341 of the Postal lottery laws. Keep a copy of these steps for yourself and, whenever you need CASH, you can use it again, and again. PLEASE REMEMBER that this program remains successful because of the honesty and integrity of the participants and by their carefully adhering to the directions. Look at it this way. If you are a person of integrity, the program will continue and the CASH that so many others have received will come your way. NOTE: You may want to retain every name and address sent to you, either on a computer or hard copy and keep the notes people send you. This VERIFIES that you are truly providing a service. (Also, it might be a good idea to wrap the $1 bill in dark paper to reduce the risk of mail theft.) So, as each post is downloaded and the directions carefully followed, six members will be reimbursed for their participation as a List Developer with one dollar each. Your name will move up the list geometrically so that when your name reaches the #1 position you will be receiving thousands of CASH in CASH!!! What an opportunity for only $6.00 ($1.00 for each of the first six people listed above) Send it now, add your own name to the list and you're in business! ___DIRECTIONS _____ FOR HOW TO POST TO NEWSGROUPS Step 1) You do not need to

re_type this entire letter to do your own posting. Simply put your cursor at the beginning of this letter and drag your cursor to the bottom of this letter, and select 'copy' from the edit menu. This will copy the entire letter into the computer's memory. Step 2) Open a blank 'notepad' file and place your cursor at the top of the blank page. From the 'edit' menu select 'paste'. This will paste a copy of the letter into notepad so that you can add your name to the list. Step 3) Save your new notepad file as a .txt file. If you want to do your postings in different settings, you'll always have this file to go back to. Step 4) Use Netscape or Internet explorer and try searching for various newsgroups (on_line forums, message boards, chat sites, discussions.) Step 5) Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in the Subject, this will be the header that everyone sees as they scroll through the list of postings in a particular group, click the post message button. You're done with your first one! Congratulations...THAT'S IT! All you have to do is jump to different newsgroups and post away, after you get the hang of it, it will take about 30 seconds for each newsgroup! **REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE CASH YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 300** That's it! You will begin receiving CASH from around the world within days! You may eventually want to rent a P.O.Box due to the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use, as long as the postman will deliver it. **JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.** Now the WHY part: Out of 300 postings, say I receive only 7 replies (a very low example). So then I made $7.00 with my name at #6 on the letter. Now, each of the 7 persons who just sent me $1.00 make the MINIMUM 300 postings, each with my name at #5 and only 7 persons respond to each of the 7 original 7, that is another $49.00 for me, now those 49 each make 300 MINIMUM posts with my name at #4 and only 7 replies each, I will bring in an additional $343.00! Now, those 343 persons turn around and post the MINIMUM 300 with my name at #3 and only receive 7 replies each, I will make an additional $2401.00! OK, now here is the fun part, each of those 2401 persons post a MINIMUM 300 letters with my name at #2 and they each only receive 7 replies, that just made me $16,807.00!!! Those 16807 persons will all deliver this message to 300 newsgroups with my name at #1 and if still 7 persons per 300 Newsgroups react I will receive $117,649.00! With an original investment of only $6.00! And some stamps. AMAZING! When your name is no longer on the list, you just take the latest posting in the newsgroups, and send out another $6.00 to names on the list, putting your name at number 6 again. And start posting again. The thing to remember is: do you realize that thousands of people all over the world are joining the internet and reading these articles everyday? JUST LIKE YOU are now!! So, can you afford $6.00 and see if it really works?? I think so... People have said, "what if the plan is played out and no one sends you the CASH? So what! What are the chances of that happening when there are tons of new honest users and new honest people who are joining the internet and newsgroups everyday and are willing to give it a try? Estimates are at 20,000 to 50,000 new users, every day, with thousands of those joining the actual internet. Remember, play FAIRLY and HONESTLY and this will really work. ** By the way, if you try to deceive people by posting the messages

with your name in the list and not sending the CASH to the rest of the people already on the list, you will NOT get as much. Someone I talked to knew someone who did that and he only made about $150.00, and that's after seven or eight weeks! Then he sent the 6 $1.00 bills, people added him to their lists, and in 4_5 weeks he had over $10k. This is the fairest and most honest way I have ever seen to share the wealth of the world without costing anything but our time!!! You also may want to buy mailing and e_mail lists for future CASH. Make sure you print this article out RIGHT NOW! Also, try to keep a list of everyone that sends you CASH and always keep an eye on the newsgroups to make sure everyone is playing fairly. Remember, HONESTY IS THE BEST POLICY. You don't need to cheat the basic idea to make the CASH!! GOOD LUCK to all and please play fairly and reap the huge rewards from this, which is tons of extra CASH. Please remember to declare your extra income. Thanks once again... "People have asked me if this is really legal. Well, it is! You are using the Internet to advertise your business. What is that business? You are creating a mailing list of people who are interested in home based computer and online business and methods of generating income at home. Remember, people send you a small fee to be added to your mailing list. It is legal. What will you do with your list of thousands of names? That's up to you." So, build your mailing list, keep good accounts, declare the income and pay your taxes. By doing this you prove your business intentions. Keep an eye on the newsgroups and when the cash has stopped coming (that means your name is no longer on the list), you just take the latest posting at the newsgroups, send another $6.00 to the names stated on the list, make your corrections (put your name at #6) and start posting again. NOTES: *1. In some countries, the export of the country's exchange is illegal. But you can get the license to do this from the post office, explaining the above statements (that you have an online business, etc. You may have to pay an extra tax, but that's OK, the amount of the incoming CASH is HUGE! And as I said, a few countries have that restriction . *2. You may want to buy mailing and e_mail lists for future CASH. (Or Database or Spreadsheet software.) *3. If you're really not sure or still think this can't be for real, please print a copy of this article and give it to someone who really needs the CASH, and see what happens. *4. You will start getting responses within 1_2 weeks, it depends. ***ALSO REMEMBER*** SEND YOUR $1 OUT TO EVERYONE ON THE LIST, EVEN IF THEY ARE NOT FROM THE U.S.

Indeed. Is it correct, however, that one should not go *too much*
higher than the maximum anticipated voltage? I read somewhere that
using (for example) 25V electrolytics in a point in a circuit where
there was only a few volts of PD could result in some sort of problem.

There's no harm in using a capacitor whose voltage rating is far above the circuit voltage.

There is one peculiarity of electrolytics that should be kept in mind, however, and maybe it's what you're thinking of. The dielectric in an electrolytic capacitor is formed and maintained by leakage current. The dielectric layer grows until the leakage current drops to a very low value, at which point it quits getting thicker, for practical purposes. If an electrolytic capacitor is run at a low DC voltage for a very long time, the dielectric layer slowly dissolves or degrades. (The length of time depends on temperature and other factors, and in my experience typically takes years for significant degradation.) If it gets thin enough for leakage to occur, it grows back until the leakage drops to a very low value -- but no thicker. So eventually, a 25 volt electrolytic, say, run at 5 volts DC for a very long time, becomes a 5 volt electrolytic because its dielectric is just thick enough to sustain that voltage with minimal leakage. If it ever again needs to sustain 25 volts, it has to be refomred by gradually raising the voltage across it to allow the dielectric to reform without undue heating. It's this same phenomenon that causes old, unused electrolytics to get leaky and require reforming.

It's considered good design practice to never expose an electrolytic capacitor to more than 80% of its rated voltage, and some guidelines recommend less.

Unfortunately, they didn't.

I'd like to thank all of you who have replied to this post for all of
your assistance. I have a strong desire to learn about wireless, but
unfortunately I took on a risk in doing so in that I've ventured
outside of the realm of my Professor's expertise and it's up to me to
figure it all out on my own. I am really hoping that the resources
you have suggested will be sufficient to enable me to get the job
done. If anyone else has anything to contribute, I would really

appreciate it. Thanks to you all...

Here is a free and open protocol... http://www.hth.com/snap/

You should learn why preambles are used when dealing with wireless
protocols. Circuit Cellar magazine (http://www.circuitcellar.com/) had an
article by Jeff Bachiochi about this in their July, 2001 (#132) issue. I
couldn't find the article on the Web, but you might be able to get a reprint
from the magazine. It is very informative.

Good luck in your project.

John

You have to have the specs of the TXRX boards and the IO. You can use x modem or y modem or z modem or several gernic file transfer protocols, kermit, just to get going. why write all that code, and figure out the timing. and fine tune it later

You may want to take this in small pieces. Get a little bit working, then
add some
additional functions. That way you have at least something to show for a
project
if the entire effort turns out to be much larger than you thought.

Think about the most basic things first:
How do you turn the transmitter on and off?
How does the receiver know if it is receiving a signal?

Since you have an RS-232 connection between each radio and it's computer,
and
are using an ASCII terminal, how do you use ASCII codes to tell the radios
what to do, as opposed to telling the radio what data to send?

Next thing to think about:
How do you send control codes over the radio link?
How do you distinguish data you want to send over the link from control
information you want to send over the link?

I think if you figure out just this much you will have a sucessful project.

I agree that a good way to start is with, e.g., XModem, since the original poster apparently has a 'virtual RS-232' connection between the transmitter and receiver going already. In fact, getting XModem or similar working should be sufficient for his project.

However, for 'real world' applications, you need to encapsulate the data in a much more robust encoding scheme -- at least if you need to go 'reasonable distances' with 'reasonable powers.' Wireless systems typically have bit error rates on the order of 10^-2 (1 in 100 bits bad), which will pretty much destroy the ability of protocols designed for 'wired' systems (TCP/IP, X/Y/ZModem, etc.) to function over any reasonable distance. Implementing sophisticated encoding with error correction would be a good follow-up project for the OP.

That is a whole study area in itself, and it gets quite complicated.
It is quite dependent upon the channel characteristics too.
The hot code now is a class called Turbo codes, invented by some frenchies.
Good luck with your project

Actually, TCP/IP probably isn't a good example, as what is on the lower
layers can be entirely different and encoded and error corrected however
you like, as long as the other end brings it back to the same data. Ok,
that's probably a bit picky, but it is true. ;^)

MSA-1023 2.5GHz 27dBm amplifiers were discontinued by HP/Agilent
a few years ago and don't seem to be available anywhere. Well,
I can get them from Hong Kong if I want to buy 200 of the things.
Does anyone here have two or three that they'd be willing to part
with? ...or know any likely parts sources? I've tried the usual
hobbyist places, but I'm not that familiar with microwave ham
suppliers. This is for repair of NMR research equipment at work.
(The big supermagnets in liquid helium are fun, but maintaining
European RF equipment is sometimes a pain.)

For real world applications, you also need to consider the multipath
problem and avoidance using e.g. by frequency diversity (e.g.
frequency hopping) or space diversity (multiple antennas or movement).

With a fixed narrow band channel in the UHF and a stationary system,
you will sooner or later be in a spot, with a 20-40 dB signal level
drop, while the signal would be perfectly acceptable with the antenna
at a location 20-40 cm away or at a frequency 100 kHz away.

Paul

Actually X and Y modem are likely to be very hard to get up on such
a system. Timing is quite critical, and turning around to listen
for an ack/nack is critical. This is one of the reasons Zmodem was
born.

Sounds like you're trying to listen for signals at the hydrogen line.
Probably would be helpful to be more specific about exactly what you're
trying to accomplish. Is an academic advisor available, or did the club
just get a bunch of (rather high-grade!) equipment donated to it with no
further guidance?

Hams involved in this type of work are often associated with the SETI
League (http://www.setileague.org/index.html). Not sure if there are
any SETI folks around the UDub or Seattle in general -- maybe you should
drop a line to info@setileague.org and see if they can point you in the
right direction, so to speak. I'm not very knowledgeable about this
stuff myself, but it sounds interesting.

It is simple.

Write down what is required; how you expect each side to behave in
response to each part of your protocol, and the program design is then
obvious.

For example, you mention packetisation. How do you propose to
encode your information such that the real data that you send is never
confuse with the start and stop of packets?

Hi Usenet,

This is a popular search. Lots of people buy tiny RF modules and then go looking for a protocol, myself included.

I looked at a lot of stuff and concluded that I was better off, and certainly from an educational standpoint, writing my own.

I have 3/4 baked 8051 pseudocode for a HDLC with digital PLL, that various protocols can be layered over. Contact me privately if your interested in it 'as is', or if you think you might like to do some work on it with me.

Regards,
Murray R. Van Luyn.

3466. AN762 amp from CCI

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-06 18:29:52 UTC
From: Michael <oz8agb@qrz.dk>
Message-ID: <418d1637$0$17610$d40e179e@nntp06.dk.telia.net>
Source record: 22250

Hi,

I built the AN762 amp along with 6 low pass filters with parts bought from Communication Concepts.

The amp itself (180W version) works fine and can easily produce 180W with 5W input.

Now to the problem and question:

I wanted to put it in a good solid case with the filters, a RX/TX relay (8A 240V Omron relay also bought at CCI) a manual switch for the filters and the filters.
I also found a good heat sink for the PA.

I connected all parts with short runs of RG-58, but a lot of the power seems to get lost in this system. If I'm lucky I can get 100W out. Even if I bypass the filters. Is RG58 a bad choice for the internal wirering? Is the manual switch a bad choice?
What special things should I address for optimum perfomance?

In my case the PA is placed on the back panel direcly mounted on the heat sink. I made a rectangular hole in the back for the PA board.
The input and output connectors are also on the back panel. The filters are mounted at the bottom of the box and connected to a band switch mounted on the front panel. Behind the filters and in front of the PA is the RX/TX relay cirucuit.

Is this HF? RG-58 should be fine. RG-174 should be fine for that matter, if this is HF or even VHF. I would suspect that you either have one defective component, a poorly attached connector, or a damaged cable.

Assuming that it's linear you could just put 5W in, let it run into a solid dummy load for a while, then feel around the input path for the hot thing. If you're losing 2 watts to one component you'll be able to feel it.

If you can you may want to feed the amp it's 5W directly and see if it still gives 180W. If it were me and I was desperate I'd yank the amp out of the case, make sure it was doing 180W on the bench, then put it back in the case checking at every step. So I'd verify 180W with it just bolted in, then verify power through the filters (accepting a bit of loss), then verify power with the case's connectors, etc., until I either found the problem or had my completed amp.

Hi all,

Thanks again for all of your assistance. Can I characterize my connection as a "virtual RS-232 connection"? I do have a pair or transceivers with serial data in/data out. I haven't gotten too much information from the vendor that sold them to me, but from what he has said, I will need to produce a transmitted waveform with apx. 50% duty cycle, for which he recommends I use Manchester Encoding. He also has explained that I need to transmit a preamble (he said a square wave for about 5 ms would do) in order to allow the receiver time to stabilize before receiving data. Without the preamble, he says I'll lose the first several characters that I transmit. He also said that I'd have to choose a pattern that I won't find in my data stream to use as my start code.

I also agree with Joel (above) that I "should" have to worry about errors as a result of this being a wireless communication. (Whether I will actually experience a reasonable amount of errors if I put the transceivers right next to each other remains to be seen, but I'd like to include error detection and possibly correction as a part of my project nonetheless.)

So, given all of this, I'm thinking that any protocol I use as a reference needs to be designed for wireless communications so as to show me how all of these needs are addressed. Perhaps I might be able to use protocols like XMODEM to observe how some common things are done (i.e. packetization).

BTW, does anyone know how to figure out how large to make your packets when designing a protocol? I imagine that if you make a packet too large, you defeat the purpose of breaking up your data and increase the chance that your packet will contain a corrupted piece. On the other hand, if you make your packet too short, you lose efficiency because your packet header overhead will dominate the size of your actual data payload. Given that, how do you pick a size in between? One way to do it would be experimental--just try some sizes and see what works. Any other ideas?

Thanks.

Hi Tim,

Yes it is a linear PA for 1-30MHz.

I did disconnect all filters etc. and just connected input and output
directly with 2 short pieces of coax. That worked fine. 180W clean output.
I'll try out your suggestion and recheck every path and see if I find the
"bug".
Thanks!

Hi Michael, Just some thoughts on your problems with the AN762.

>I connected all parts with short runs of RG-58, but a lot of the power seems
>to get lost in this system. If I'm lucky I can get 100W out.
The short runs of RG-58 should not produce any noticeable loss. I would look at Tx/Rx relay and the filter bandswitch.
Another thing to consider is how you determined the power gain of the PA before and after you put it in the enclosure. Make sure all the measurement parameters (frequency ect.) are exactly the same.
Another thing to remember is that the circuit board is the only thing that has a power gain. All the cabling, switches, and relays will have some loss. If you are losing 80 watts, it is probably in one section, and it should get pretty hot. Of course the circuit board will get hot, it does in normal operation. Look for some of the stuff you added getting hot. Also does the circuit board get hotter now than it did before you enclosed it?

> what works. Any other ideas?

The zmodem protocol used back in the latter days of phone bbs's used a variable packet size. If you were getting lots of errors, it would drop packet size down till some packets got thru without an error, if later it detected that all packets were getting thru without errors, it would up the packet size to increase thruput. If it got down to minimum packet size and still had at least one error per packet it would abort the transfer. If you include some form of error correction along with the packets then you lose another 30% or so of thruput, but you can survive simple bit errors, and it takes a multiple bit error to be unrecoverable. And when I speak of errors I refer to unrecoverable errors, that the error correction couldn't fix.

Error detection is mandatory for any sort of packetized communication.

You might also check out the code used by modems around the time of v22.bis (2400 cps modems) and later. Most of them offered error detection/correction and data compression which meant the data was packetized.

3474. Help! Transformer induces hum to chassis!

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-07 06:55:00 UTC
From: Prune <bobysgotguns@yahoo.com>

Source record: 22258

I'm poor. So I rebuilt the core of a 16 lbs microwave oven transformer and now it's very quiet -- outside the chassis. I mounted it in the 3u power supply chassis, and the chassis resonates like crazy, at least 30 dB more noise than the transformer alone. Rubber/springs/foam didn't help much. I spent quite some time building a pneumatic vibration isolator with a pump and everything. Imagine my surprise when it turned out most of the vibration wasn't transmitted mechanically...the hum was being induced electromagnetically into the chassis! I almost cried! Repositioning didn't make much difference (more of the effect seems to come from the side with the primary winding, but orienting that side away from the vertical walls means having the core horizontal, which makes the hum worse; standing the transformer on its narrowest side doesn't fit in the chassis). All my testing was done with no load as the salt water resistor boiled too quickly and I took it apart. Would it get better/worse/same when it's loaded? And what can I do to deal with the issue, in terms of shielding or anything else? I swear I'm going to go crazy trying to figure this out.

If the filter bank is on the rear panel and the filter switch is on the front panel, it sure sounds to me like that long, circuitous path could be the problem. I'd try eliminating the filter switching and see if the performance returns to normal. Also be sure that whatever surface the connectors are mounted on have a very good and short ground path back to appropriate place on the board.

3476. Variable Capacitor Supplier

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-07 11:16:19 UTC
From: S C <cromie@onetel.com>
Message-ID: <418e0484@212.67.96.135>
Source record: 22260

I am in the process of designing an ATU yet am having difficulty in locating a company who can supply a suitable Variable Capacitor.

At the moment the only ones I seem to find are trimming capacitors and I require an item which is somwhat larger than that - E.g in the region of about 680pF.

Any suggestions as to a suitable supplier would be grately appreciated.

Failing this if anyone knows of a circuit diagram available on the net which may be constructed from components more readily available then I am more than happy to hear from you.

Many Thanks.

There are several US manufacturers still in business (a google search will turn up at least 3), one option is Oren Elliott Products (OEP) in Ohio.
http://orenelliottproducts.com/index.html

OEP was the original supplier for many Collins, Drake and Heath capacitors (and planetary drives).

Oren Elliott Products, Inc. is the largest US domestic manufacturer of air-dielectric variable capacitors.
Producing capacitors since 1925, the OEP Plant I was first known as American Steel Packaging Company and then as All Star Products. In those early years, their applications and major products were almost exclusively focused on the broadcast and short-wave radio industry (which was a huge market in late 1920s and 1930s - Hammerlund, Hallicrafters, Zenith, etc.).
During World War II, ASP supplied the Allies with 3500 capacitors per day, and by the end of the war the company was the world's largest producer of air trimmers.
In 1983, Oren Elliott Products Inc.(name change from ASP to OEM) was created and expanded into new facilities (Plant II) to include CNC lathes, CNC vertical machining centers, CNC and conventional Swiss screw machines, and all of the support equipment necessary to enable OEP not only to produce all of the machined subcomponents for their capacitors.

Another option (UK based) is Jackson Brothers which was founded in 1923 to manufacture variable capacitors and accessories such as tuning drives and dials. Today, distribution and production facilities are owned by the Mainline Electronics Group.

Learn to love hum. Let's face it: it's not as if your oven's going to
be running 24/7!

A little ally-bashing and you have your own capacitor to your
own specifications! A trivial matter for a _REAL_ Radio Ham; perhaps
more difficult for a CBer who buys his station from the shops and
takes it back to be mended?

Microwave oven transformers operate with parts of the core very nearly
saturated during parts of the cycle, so they spray magnetic fields all
over the place. Any iron in their neighborhood will be bumped around
like a vibrator. Does your unit still have the magnetic shunt between
primary and secondary? Is the primary the same number of turns it
was, originally? Adding more primary turns (lowering the volts per
turn) will help. Wrapping a thick band of copper around the core in
the direction the turns wrap (an eddy current shield) may help contain
the stray fields a bit, also, at the cost of more waste heat and less
efficient heat removal.

You could try reinforcing the chassis with some 1/2 inch aluminum angle
bolted or riveted across a long span of metal. You won't change the
forces being exerted on the chassis, but you may move the resonant
frequency up enough so it doesn't get much excitation.

Access the Ocean State Electronics website at www.oselectronics.com
and you will find a number of variable capacitors (two pages worth in
their printed catalog). Their VC-250 and VC-2502 models are good
for just over 3 KV voltage breakdown. Quarter-inch shafts, almost
10 1/2 inches long. Inexpensive, no. Price is $70 and $80,
respectively.

Smaller (lower voltage breakdown) single to multi-gang units are
available including a 4-gang which can be paralleled to get
800 pFd maximum.

Ocean State also has a number of hardware components for
rotary components from shaft couplers through panel bearings
through flexible shafts and on into vernier reduction drives.

Source record: 22272

I have bought many many items from Ocean State and I have never been let down.

I have several of their dual gang 365pf air variables here for monkeying with crystal receivers and the like. Put them in parallel and add a series gimic cap and you could be at 680pf pretty quickly.

(730 * X) / (730+X) = 680
(730 * X) = 680 * (730 + X)
(730 * X) = (680 * 730) + (680 * X)
(730 * X) = 496400 + (680 * X)
(730 * X) - (680 * X) = 496400
50 * X = 496400
X = 496400/50
X = 9928pf

So go with a .010 uF cap in series and you'll be cooking with gas.....if I did my math right.

The AmQRP club has a new DDS VFO kit available.

See http://www.amqrp.org

I think they just added it a few days ago.

I've been very happy with all the kits I have bought from AmQRP.

It's not mounted in a microwave; it's being bridge rectified into a CLCRC filter for plasma supply. I get 3 kV DC unloaded. I need to have it in a chassis as otherwise it makes too much stray interference.
I was thinking of mu-metal foil but those are too thin and would probably saturate and be ineffective. Using a thick shielding on the other hand means the shielding will be rigid and buzz instead of the chassis, plus it presents a cooling problem. I've seen transformers where only the exposed windings are shielded, with the outer part of the core exposed. Maybe that will provide enough cooling. I belive they fill those with epoxy for improved thermal exchange. I need to pull 350-400 mA DC and the chassis has a fan.

Ebay user ID: righteous-jude

I'm selling a FM Stereo transmitter which is well-known as being the best transmitter you can get for the money. It is fully assembled and not a kit. You'd have to buy a commercial brand FM exciter (such as a Harris) to exceed the specs of this unit. On virtually all FM receivers you would not hear the difference.

You could hook up and transmit any sound source you want, such as:

1. The sound output directly from your computer (to play MP3's) using iTunes or any software you like.

2. Directly connect an iPod, CD Player, tape deck, etc. right to the transmitter.

3. Use a professional mixer board. A decent Behringer UB802 Mixer is only $49. Then you could mix and cross-fade between two different stereo sources LIVE. Add a decent microphone ($19) so you can talk and people won't know you aren't a commercial station until they realize "Hey, why aren't there any advertisements?"

This FM transmitter is DIGITAL (not analog) and can equal the sound of commercial FM stations. It can transmit anywhere between 88-108 MHz. It outperforms ANY of the Ramsey or other so-called "kit" transmitters, including the "export" version of the FM-100B which Ramsey sells for $429.99 - which is WAY more than the cost of the transmitter I'm selling.

Depending on the quality of the antenna you connect to it and how high up in the air it is, it is possible to get about a 1.5 mile range using a simple homemade antenna, or over 5 miles of range with a $100 pre-made roof-mounted antenna.

This transmitter has a filtered RF output which means it puts out a clean signal. RF filtering is important to avoid interfering with other FM stations, or if you intend to add an RF Power Amplifier to increase your range. Most other low cost FM transmitters have bad RF harmonic supppression which means they cause a lot of interference to TV's and

radios in your neighborhood, which will attract attention to you from people like Cable TV technicians (something you definitely want to avoid).

I won't list all the details here, you can learn them all by going to http://www.Ebay.com and entering item # 5730774971 using Ebay's "Search" feature. It will be available for the next 7 days.

Here's a link for info about a good, affordable audio mixer:

http://www.musiciansfriend.com/srs7/g=rec/search/detail/base_pid/631238/

And lastly a good inexpensive microphone:

http://www.musiciansfriend.com/srs7/g=live/search/detail/base_pid/270490/

You'll also need a mic cable:

http://www.musiciansfriend.com/srs7/g=live/search/detail/base_pid/332001/

A suitable 10-foot XLR mic cable is $10.

http://www.musiciansfriend.com is a good, reliable and affordable Internet seller of music-related gear. If there is one located in your area, Guitar Center also carries this gear.

To avoid unprofessional noise while talking, don't hold your microphone, put it on a desk stand. The best deal for this item is, believe it or not, the Radio Shack model 33-370 for only $7.99.

Peace,

righteous-jude

Hi all,

When was the Handbook last produced in hardback? I want to try to buy
the last h/back edition as the paperback one sucks.

Thanks,

p.

Why not buy the current edition and get it bound by a bookbinder. It'll be
expensive but it'll last for years. 8-)

> These are your only 2 reasonable solutions.

Adding more turns to the primary -- will just a few % more turns make a difference? I don't want to loose too much voltage. Also, I hope it's not too important to match the gauge of the added turns to the rest of the primary, as I don't have that exact gauge solid wire.

My original shield/epoxy question remains.

> or is it just *way* over the top?

Sure. *IF* you like sparks around your rig. Make a Jacob's Ladder, etc.
Lotsa volts, don't need to much ma.
This thing belongs on rec.electronics.how.big.can.i.make.a.spark

There are guys who make REALLY BIG Tesla coils. I'm talkin' make your own
capacitors, 5-7 feet tall, light the neighbor's florescent bulbs big!

I kept the ignition transformer from my mother-in-laws oil furnace when
converted to gas. There's quite a bit of power there. The tips of my
Jacob's Ladder heated enough to melt the plastic tube I had it in...and they
barely touch it.

The RSCB is the Radio Society for Citizen's Band, a Britland
book publisher based in Potter's Bar.

The RSCB is irrelevant to Ham Radio despite the false claims that
they make to the contrary.

They promote CB such as the M3/CB Fools' Licences.

You're right, we Americans no longer care about the rest of the world. When we did, by feeding them, fighting for them, helping them rebuild, etc. The rest of the world crapped on us. Twice in the last century we had to save the damn Europeans in two World Wars. We give and give and give to countries starving and in need. We send our forces to restore peace. We help in earthquakes and famines.

So since we have always helped Europe and now Europe turns it back on us when we are in need, screw you all. Have a nice time fighting World War III by yourselves. We'll sit that one out thank you.

Hi Michael,

Do you have any photos of your amplifier? I am building an amplifier
based on the AN758 kit and filters from CCI.. 300W from a 48V supply. I
am looking for ideas for mounting the boards in the box etc.

Hi,

Not wanting to pour rain on the parade but -

Diagnostic x-ray transformers are only rated for very intermittent use and are normally immersed in oil for cooling and insulation purposes.

The meter in the picture is calibrated in mAs (not mA) so it isn't obvious what the actual secondary current is. FYI, the milli-amp seconds figure (tube current x exposure time) is preset and used to set film darkening.

An x-ray tube is a temperature-limited vacuum diode so that the current can be tightly controlled. Therefore, during the arc shown, the secondary voltage will almost certainly have dropped quite dramatically.

Cheers - Joe

Thanks for the info, knew it was time limited, but not the oil immersion
stuff.
It is built strange for a HV TF, probably optomized for the time and tube.
Ones I have seen are cubic foot black things.

The stray field will probably go down faster than the proportion of
windings added. Any wire as heavy or heavier can be used.

If you don't want to lose secondary voltage, you can just add the same
proportional number of secondary turns, too.

Going in the other direction, I remember as a kid playing with a giant step down transformer (the largest one Lionel made for their train sets). If you put a common #2 pencil into the circuit (from end to end using the full length of the pencil) the lead (graphite) would glow white hot and the wood would catch fire.
Wonder how many amps I forced into the pencil?

Nice NOS porcelain 2 piece feedthrough insulators. Require 3/4 inch chassis hole. These are great for hb tuners, linears, hv supplies, and balanced line antenna feedthrough window plates. I have several left but way more than I now can use so I will priority ship them at $30 for 24 insulators. I have a photo. 73s-Lew/K1NDV

It gets into more of the low level detail than you might, perhaps, be interested in for this project, but I'd recommend Bernard Sklar's book, _Digital Communications: Fundamentals and Applications_ for a very good book on the basics of that topic. Second, if you do elect to design your own protocol, I'd recommend modelling it before you deploy it. You can find errors quickly and easily in a model that you might only rarely encounter in real operation. To find out more about that, I'd recommend Spin, which you can read about at http://spinroot.com/spin/whatispin.html

Good luck!

Ed

3540. LED Pushbutton Switch

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-12 02:32:53 UTC
From: Jim - KK1W <kk1w@arrl.org>
Message-ID: <10p886mcthon684@corp.supernews.com>
Source record: 22223

I'm looking for a source of LED pushbutton switches for use in a model railrad application. I've seen similar ones in vehicle alarm installations but can't seem to find anything on the web.

They need to be NO type and not very large. 3mm or so is fine. Price is important as the application will require quite a few.

Thanks for any info,

Jim, KK1W

Anyone else have trouble with HF - tripping GFCI in my garage when keying the mike.

3542. For Sale: FM Stereo Broadcast Transmitter 88-108 MHz Digital PLL LCD Display - 2 Watt

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-12 08:05:28 UTC
From: righteous-jude <nospam@noreply.com>
Message-ID: <BDB9BCD8.4ADD%nospam@noreply.com>
Source record: 22225

FM Stereo Broadcast Transmitter
Digital PLL - LCD - 2 Watt RF Output

Ebay item # 5730774971

Auction ends in 2 days:
Ends Nov-14-04 19:13:56 PST

Here is the direct link:
http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=5730774971

Transmitter is an assembled and tested unit -- not a kit.

This FM Stereo transmitter is well-known to many eBayer's as being the best transmitter you can get for the money. You'd have to buy a commercial brand FM exciter (such as a Harris) to exceed the specs of this unit. On virtually all FM receivers you would not hear the difference.

This transmitter is a NEW design and DOES NOT use the "BA" or "Rohm" analog chip - ANYWHERE IN IT AT ALL. Which is a good thing.

The heart of the transmitting circuit is a Cypress Semiconductor Digital Signal Controller. This is a 16 bit DSP microcontroller with on-chip Flash, RAM, A/Ds, PWM, and 200k of EEPROM.

This transmitter can equal the sound of commercial FM stations. It outperforms ANY of the Ramsey transmitters, including the "export" version of the FM-100B which Ramsey sells for $429.99.

You can have this transmitter for much less than that.

Here are the specifications for this transmitter (from the manufacturer):

Transmission Frequency: Adjustable between 87-108 MHz
Tuning Steps: 10 kHz
RF Power Output: Typ 1Watt @ 13V or 2 Watts @ 24V
Spurious RF Emissions: Better than -45 dB ref. to carrier
Frequency Stability: PLL Typ +/-1KHz
SWR Ruggedness: Withstands 30:1 SWR mismatch
RF Output Connector: BNC type
Audio Input Sensitivity: 0.8V rms for +/- 75 KHz deviation
Signal To Noise Ratio: 60 dBu
Frequency Response: Flat from 20 Hz to 15 KHz
Stereo Separation: >40 dB
Pre-emphasis: 75 uS (standard FCC spec for U.S. FM radio)
Audio Distortion: Better than 0.2 % THD

Audio Input Connectors: RCA Phono Jacks
Power Jack: Coaxial type, 5.5mm O.D. 2.1mm I.D. center positive
DC Power Input: 12 to 24 Vdc Regulated 600mA

The transmitter has a built-in user options menu system with two buttons for adjusting operating parameters such as transmitting frequency, modulation level, MPX pilot level, etc.

This transmitter has a clean RF output. The design includes a seven-element Low Pass RF Filter for harmonic suppression.

This transmitter has built-in audio AGC (Automatic Gain Control). The AGC feature can be adjusted using the user options menu or you can turn it off if you like.

Operating instructions will be included with the unit.

I don't have trouble with HF tripping the GFCI in YOUR garage, but I sure as hell have a similar problem here in my shack.

Cheap shots aside, the GFCI usually contains a toroidal core which has the active and neutral (return) lines pass through it, and a secondary winding which sees the difference between the active and neutral currents i.e. the current passing through another route (ground assumed). The secondary feeds an amplifier which drives the trip circuit.

In an endeavour to obtain decent sensitivity AND fast reponse, there appears to be a general lack of RF immunity in these devices.

If I use a VHF handheld within a metre or so of appliances connected via the GFCI, no problem. However if I use the same device sitting in its mains-powered charger base - on or off charge - the interrupter trips. I also have a 25W transceiver on 80 MHz (commercial) which caused frequent tripping on Tx until I took remedial measures.

<presumption mode> Enough RF is conducted along the power lead to result in RF in the toroid's secondary which the amplifier rectifies/detects. </presumption mode>

In the case of the 80 MHz set, I slipped a toroid over the DC power lead. (RF choke). DC power is derived from a mains PSU. Antenna is not earthed to this system. Problem gone.

In your instance, it may be RF entering by direct radiation from the antenna into the GFCI or power cables passing through same, OR it may be RF getting conducted back up the supply of the HF set. Trial and error should determine which - does it trip when you run the Tx into a dummy load? Can you try a toroid around the supply cable?

3544. Looking for roller inductors

The power company run a line to my house. They supply me with
electricity. This amounts to a 230V, 65A facility at the distribution
board in a cupboard under the stairs. I run all my stuff from that
board. The board contains several RCBOs that trip-out in the event of
any leakage current being sensed. If current in = current out; they're
happy and won't trip. Because they don't trip out, I conclude I don't
use any current.
The voltage supplied is 230VAC RMS. Since this is alternating between
equal positive and negative half-cycles, the average level of this
voltage supply is zero.
I use no current and they effectively supply no voltage. Why do I get
billed for electricity usage when I clearly can't have used any?

You don't get billed for current, you get billed for energy - in the
UK the measure is the kilowatt hour. Multiply your voltage by your
current instant by instant, take the average (gives you power) and
multiply that by the duration in hours and you have your consumption.

NIce try, though...

No, you don't use hardly any leakage current to earth (RCD), and you
don't use more than the maximum trip current between lines (MCB). An
RCBO is an MCB + RCD, to use the Brit terms.

>The voltage supplied is 230VAC RMS. Since this is alternating between

But the RMS value is 230VAC.

>I use no current and they effectively supply no voltage. Why do I get

Why don't you ring up the power company engineers and see if you can
get them to see things your way? Could save a lot of money.

An interesting tale of GFCI and RFI. Square D was/is a manufacturer of those little devils. In manufacturing they had a test table where they took representative samples of the weeks manufacture and ran them under load for some period of time. These would operate satisfactorily for some extended period and then the first of the week they would find a large failure rate. At times, as much as 50 percent of the run had "failed".

Eventually, they found that the plant closed for the weekend, and the guard in making his rounds would check in on his walkie talkie at a reporting station located adjacent to the test table. The miniscule amount of RF would trip those suckers and caused Square D to incorporate some RFI protection.

I have tripped mine causing the street lamp to fail (among other circuits) but only when running high power on 2 meters. (KW level) If you're failing yours, it's most likely quite old, either manufactured before they recognized the problems, or having failed whatever protection that was built into the module. Would suggest that replacement with a new one from your local electric supply house will cure the problem.

Its interesting this topic came up this week. At work (NASA's Johnson Space Center) I've been working an issue related to a GFCI circuit on the International Space Station. Seems ESA (European Space Agency) has built a GFCI circuit into their UOP (Utility Outlet Panel) which, just like all other GFCI's, monitors the safety wire for excess current in order to protect the crew, etc.

Unlike your residential GFCI circuits, the UOPs are for DC, not AC. It turns out that with some of the EMI filters we put on our loads, you could get enough significant ringing off the L-C filters to trip the UOP. Yet another problem that you can run into with GFCI, only in the DC world.

Just thought I'd throw that one out there.

For a purely resistive load, since P = Iï¿½R, the sign of the current
going into the load gets squared, so that when it goes in negative it
comes out positive.

For a reactive load, you don't get charged for the imaginary current,
(at least in the US we don't) so you get charged for what you use.

What you want to do is take an extension cord, plug it into an outlet on one side of the house, and plug the other end into an outlet on the other side (carefully observing polarity), thereby sending their own electricity back to them, running the wattmeter backwards and nulling out any billable KWH.

Bob

BTW, just in case, this is a *JOKE*, and it wasn't me telling it.

>average of zero, you will start paying your bill with a combination of
>payment and charge back. That should straighten them out.

The way it was explained to me, the electric company sends you the stuff on one wire, but it goes right back to them on the other wire. You should only be paying a small rental fee, as you don't get to keep any of it, and they keep re-selling the same electricity back to you and everyone else.

They don't bill me instant-by-instant; they bill me for the power they claim I've used over the course of a three-monthly period. Since power is the product of voltage and current (and I've proved earlier that both are zero) I'm being charged for electricity that I've not actually used. The current goes in and out of the house unchanged. It's all returned to the power company. All I've done is borrow it. And you can bet that when they get their current back they don't just dump it to ground; oh no. They re-sell it again and again and again to other suckers like me. We're all paying multiple sums for the *same* lousy current that's probably been circulating for years.
The power companies have been scamming us for decades! I can't believe I've only just woken up to it.

Aww c'mon - if you multiply a positive voltage by a positive current
you get positive power. If you multiply negative voltage by negative
current you get positive power.

Anyway - are you cleaning and refurbishing those amps before you give
them back? They wear out, you know.

Because free energy is against one of the laws of thermodynamics - can't
remember which...
As everybody knows, you get fined for doing illegal things ;)
That's what your power company is doing.

Regards
Markus

Sorry, Don, you obviously haven't thought this through. Since *all* their current is returned, I cannot have used *any* of it. Whatever the voltage might be, multiplying it by zero Amps still gives zero power!

>Anyway - are you cleaning and refurbishing those amps before you give
>them back?

Why should I? That's *their* job. I pay enough!

>They wear out, you know.

You mean they like lose their charge after a while? That would make sense as I've found as years have gone by, I've had to turn the heating up more and more. The thieving bastards!

Thanks, Doug. I'm glad *someone* here has some sense!
And another thing: many of us here in Britland use earthed neutrals,
so the power co. gets it's current back via earth alone. I don't mind
my own current being returned via my own garden, but why the hell
should everybody else's' current pass through my land en route back to
the power station? If the telephone company wanted to run a line over
my property, they'd have to pay me for the privilege (it's called a
"wayleave") but the power co. are paying me *nothing* for all the
other customers' earth returns running via my garden. What a rip off!

That's not how they do it.

Since they know that they'll get back every bit of current they send
you, they keep track of what they send you for three months, normalize
it to 1 and call it "a", call what you send them back "b", and then do
the followwing maths:

normalize a:
a = 1

set b = a:
a = b

multiply both sides by a:
aï¿½ = ab

subtract bï¿½ from both sides:
aï¿½ - bï¿½ = ab - bï¿½

factor both sides:
(a + b)(a - b) = b (a - b)

divide both sides by (a - b):
(a + b)(a - b) = b (a - b)
-------------- -----------
(a - b) (a - b)

remove terms which cancel ((a -b)) from both sides:
a + b = b

convert:
1 + 1 = 1

So, you can see that the sum of the amount they sent you and the
amount they received back _has_ to be the same as the amount they sent
you, and that's what they bill you for.

Source record: 22150

[I originally posted this two and a half years ago... we'll see if I have any better results this time...]

Hi,

Has anybody heard of the booklet, "RF Oscillator Circuit Analysis and Design with Breadboard Experiments" or of its author, one John Plastonek? I purchased a copy of this booklet back in 1999 from an ad in the back of Nuts & Volts and really like it. For me, Plastonek hits just the right blend information, and having breadboardable circuit designs that have all the components values calculated is a tremendous benefit compared to textbooks that leave it up to you to bridge the gap between theory and practice.

Unfortunately his company, listed as "RFLS, P.O. Box 9185, Gaithersburg, MD 20898-9185, phone (301) 528-6671" is no longer around, and his e-mail address of efls@wordlnet.att.net just bounces. The reason I care is that the last page of this book claims there are -- or would be -- other booklets titled:

"Crystal Oscillator Circuit Analysis and Design with Breadboard Experiments"
"RF Receiver Circuit Analysis and Design with Breadboard Experiments"
"Frequency Synthesizer Circuit Analysis and Design with Breadboard Experiments"
"RF Amplifier Circuit Analysis and Design with Breadboard Experiments"

...and I'd very much like to obtain copies of them if they actually ever did see the light of day.

Does anyone know whatever might have happened to Mr. Plastonek and his booklets?

Thanks,
---Joel Kolstad

Simple.

Electrons come into your house (supplied by the utility) and then they go back out.

You don't buy them - you just pay rent for the time you have them.

Well, you have 'em in your house whether they're being pumped around,
or not.

It's more like a turnpike - you pay for the amount of distance driven,
times the number of vehicles that you drive. Doesn't matter whether
you're driving north, south, or north-and-then-south again. You
drive, you burn gas, you pay the toll.

Paul; You could drive ground rods into opposite corners of your property
and extract some of the power from the earth and run your house for
nothing at all! In fact If you dig a deep enough trench in the middle,
you could isolate the ground and get a bigger return current!

Two things flow along wires: charge and energy. The energy flows fast,
while the charges flow slowly. The charges flow in a complete circle
(you don't use any up,) while the energy is absorbed by your appliances.

OK, here's the big question: which one is the electricity?

If an electric current is a flow of electricity, then "electricity" is
not energy, and the utility companies neither produce nor sell any
electricity.

It all depends on how we define the word "electricity." And unfortunately
the reference books don't agree with each other. Some books follow
the scientists of old, and define electricity as charge (so a quantity of
electricity is measured in coulombs, and a flow of electricity is measured
in amperes.) Other reference books ignore that definition, and instead
they insist that electricity is energy... so a flow of electricity is
measured in watts, not amps.

> The voltage supplied is 230VAC RMS. Since this is alternating between
> equal positive and negative half-cycles, the average level of this
> voltage supply is zero.
> I use no current and they effectively supply no voltage. Why do I get
> billed for electricity usage when I clearly can't have used any?

The path for electric current is CIRCULAR. For every bit of charge that
the electric companies force into your appliances, an equal amount of
charge goes back out through the other wire. The current is also
oscillating (the charges don't actually flow, instead they vibrate
back and forth over extremely tiny distances.)

On the other hand, the path for electrical energy is one way. The
electric companies send electromagnetic energy over enormous distances.
It's this energy which your appliances consume. Unfortunately for
our definition of "electricity," this energy is composed of electric and

magnetic fields, and it travels in the space surrounding the wires. Do we really want to state that electricity is made of EM fields? Do we really want to say that no electricity travels inside of wires, but instead it travels in the space outside? If we say that electricity is a form of energy, that's the same as saying that electricity is just some travelling waves of electromagnetic field.

Possible solution: never use the word electricity at all. If you want to say that electrical energy flows along a circuit, then say exactly that. If you want to talk about flows of charge, then speak of charge and not "electricity." As long as we never mention the word "electricity," then amperes and watts are no longer mistaken for each other, and we can get on with explaining the joules and coulombs in ways that make sense.

Er, ????

You get billed for "Power Consumed" which is covered under the umbrella of "Energy". Now POWER is consumed when a voltage potential causes a current to flow in a circuit. If that circuit happens to be through a heater or refrigerator then CURRENT flows. Since the supply voltage is constant (or should be) then the load requirement determines the current which flows and in some cases it will be small and in others it will be large. Now since CURRENT x VOLTAGE = POWER, you do get charged for CURRENT usage and the amount you get charged varies dependant upon how much current flows and for how long.

Paul, perhaps you should be a politician...

What you are charged for is the use of the current as it flows through your appliances etc. Because the current flows in your appliances it places a load on their generating plant. Because millions of houses are also doing the same thing at the same time the load on the generating plant is enormous and in order to supply the large amount of current required by all users (yes, even though they do get it back in the return feed), the generating plant has to be enormous itself. Now, power stations aren't something you pick off a tree, they have to be built and maintained and they consume "energy" in order to be able to generate the large amount of current which flows.

Now even a dill can see that the cost of building and running the plant has to be paid for and the cost of doing this is usually amortised over a period of 15 or 20 years and after that it is pure profit. So you are paying for the current which flows through your systems to generate heat, cool and cook your food, run your stereo etc, etc. Now despite your fallacious arguments about supply voltage summing to zero and the supply authority getting all their current back after having gone through your house, you can't argue that you shouldn't be charged purely for no other reason than the law stating the conservation of energy.

"Energy can neither be created nor destroyed, but may only be changed from one form to another."

The supply authority is changing one form of energy to another in order to generate electrical energy and you are changing the energy

they supply into other forms required to generate heat, cooling etc in your household. I can tell you this, converting energy from one form to another doesn't come free and not even a politician would be stupid enough to believe that it does.

An old-timer I used to know made his own from plastic drain pipe. He used a lathe for cutting a spiral grove in the pipe for the wire, and machined most of the other parts himself.

I'm not sure I'd qualify anything requiring a machine lathe as being
"simple".

Seems like there's an opportunity for free energy kooks there.
Put positive and negative current in alternately, averaging zero,
but get all positive power. :-)

Yes, there's an extra fee if you keep any half cycles without returning them on the following half cycles. It's called the Semi-Unused Cycle Kinetic Electricity Return fee.

Be thankful that you have ac power coming to your home. Back in my days in the old country, I used to walk 5 miles through snow and sludge in the middle of winter to go to the next village to buy a couple of batteries so that my father can listen to his nightly stories on our wireless. :P

Huh? It's only 5:30AM here and I just got up but, the ONLY time you aren't consuming power is at the zero crossing of the voltage and current sine waves (assuming a purely resistive load where I and E are in phase). Since you are paying for power, which is P=I X E, during the negative half cycle, you have, for example, -168 Volts X -1 Amp = +168 Watts...try it on a calculator...negative times a negative is positive.

It is if one has a lathe. 8-)

Strictly speaking, he wasn't making roller inductors, anyway, as the contact
was moving across the turns giving one turn resolution, like a rheostat. He
only used QRP. Making a proper roller inductor for high power like those
made by Henry would be quite difficult.

Well, you can look at it this way...It's basically a series circuit, from generator, through all customer houses, and back to the generator. You may be returning ALMOST all of the current coming into your house, minus resistive losses, but if you divert that voltage and current through one of your appliances, the voltage and current (hence power) will actually be doing some work. Electricity, while being USED in your house, is like an employee of YOURS...it is doing WORK, so legally you must pay the worker's wages for work performed. Just be glad you don't have to pay it's social security taxes, fed and state taxes, health insurance, worker's comp insurance premiums, 401K contributions, etc. Starts to make electricity (employee) sound cheap.

The Museum of Science in Boston has a bunch of similar toys in their
Thomson Theater of Electricity. http://www.mos.org/sln/toe

The large Tesla Coil they have is rather large, 8 feet tall and 4 feet
across. The smaller ones are 75,000 volts.

They also have a two story high Van de Graff generator.

They do regular demos of all this several times each day.

The website above includes a picture gallery.

Yes please, guided energy!. It seems fathomable and sits easily amongst
waveguides, aerials, lightbulbs and triphasic conduit.
Electrons have a bit of weight. If you spin a metal disc at the power
station fast enough, then all the electrons in it should centrifuge out and
crowd towards the outer edge leaving no electrons in the middle. The
electrons aren't happy being herded onto the outer rim and really just want
to hang out and chew the cud. The potential to do work has thus been stored,
just like in a flywheel.
Paul switches on his TV and gives them a route back to the disc centre. The
stored disc energy is immediately translated in his TV to heat, light and
sound as the electrons all work through to become nonentities again.
The power station people don't like this as all their patiently herded
electrons have escaped, the disc has slowed a tad and they have to raise
more steam to maintain speed and herd more electrons. Hence will charge
Paul handsomely for his profligacy.
Dunno what happens in a spinning capacitor with diode connected plates
though :-)
regards
john

Thanks, Scott. So you're basically agreeing with me. I owe the power
co. for the positive cycles they send me; they owe *me* for the
negative ones. Since they are equal and opposite, they cancel each
other out. Overall, then, zero billing justified.
We are being conned!!!

Well, I don't see how that could work, but I had considered digging a
trench around my boundary and thereby cutting off the return path for
the other users' behind my house and demanding payment from the power
co. to re-instate it. But then it's obvious the return current's only
going to go deeper underground or around my property. It seems there's
nothing I can do to make any dough out of this. :-(

You might have a case if the ac feed was a single line- but the
so-called negative cycle is a relative polarity- they draw current out
of your hot connection by supplying it to the neutral. They vector sum
of the two currents they deliver is zero at all times- so you pay for
them to maintain an undulating line voltage with constant RMS magnitude
across your house.

I hope you should know the answer. It involves a square term.

Have you tried measuring the voltage.

No European countries run on 230V to the best of my knowledge.

EUREKA!!!

The fallacy lies in your thinking that the power company bills you for
what they send you, when in actuality what you're getting billed for
is what you send back to them!

Consider: they send you a bunch of positive and negative cycles, but
as long as you don't turn a switch on anywhere, those cycles can't
travel back to the power company, so you don't get billed for them.

However, when you do turn on a switch you're providing a way for
their electricity to get back to _them_ and stop beating it's head
against an open switch, so it seems to me that they should pay _you_
for doing them the courtesy of returning their electricity.

Polarity is no more than direction of flow. They send you electrons on one lead, then electrons on the other lead, making twice the number of electrons, so you gvetting them for 1/2 price as they only count them the once:-)

3607. Auction ends in 1 day! FM Stereo Broadcast Transmitter 88-108 MHz Digital PLL LCD Display - 2 Watt

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-13 19:40:38 UTC
From: righteous-jude <nospam@noreply.com>
Message-ID: <BDBBB146.4F7C%nospam@noreply.com>
Source record: 22191

FM Stereo Broadcast Transmitter
Digital PLL - LCD - 2 Watt RF Output

Ebay item # 5730774971

Auction ends in 1 day!

Ends Nov-14-04 19:13:56 PST

I have updated my Ebay auction listing to include an MP3 sound file you can download which is an ACTUAL recording of how the FM transmitter sounds on-the-air.

Here is the direct link:
[URL=http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=5730774971]http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=5730774971[/URL]

Transmitter is an assembled and tested unit -- not a kit.

This transmitter design DOES NOT use the "BA" or "Rohm" analog chip - ANYWHERE IN IT AT ALL. Which is a good thing.

This transmitter can equal the sound of commercial FM stations. It outperforms ANY of the Ramsey transmitters, including the "export" version of the FM-100B which Ramsey sells for $429.99.

You can buy this transmitter for much less than that.

Here are the specifications for this transmitter (from the manufacturer):

Transmission Frequency: Adjustable between 87-108 MHz
Tuning Steps: 10 kHz
RF Power Output: Typ 1Watt @ 13V or 2 Watts @ 24V
Spurious RF Emissions: Better than -45 dB ref. to carrier
Frequency Stability: PLL Typ +/-1KHz
SWR Ruggedness: Withstands 30:1 SWR mismatch
RF Output Connector: BNC type
Audio Input Sensitivity: 0.8V rms for +/- 75 KHz deviation
Signal To Noise Ratio: 60 dBu
Frequency Response: Flat from 20 Hz to 15 KHz
Stereo Separation: >40 dB
Pre-emphasis: 75 uS (standard FCC spec for U.S. FM radio)
Audio Distortion: Better than 0.2 % THD
Audio Input Connectors: RCA Phono Jacks
Power Jack: Coaxial type, 5.5mm O.D. 2.1mm I.D. center positive
DC Power Input: 12 to 24 Vdc Regulated 600mA

The transmitter has a built-in user options menu system with two buttons for adjusting operating parameters such as transmitting frequency, modulation level, MPX pilot level, etc.

This transmitter has a clean RF output. The design includes a seven-element Low Pass RF Filter for harmonic suppression.

This transmitter has built-in audio AGC (Automatic Gain Control). The AGC feature can be adjusted using the user options menu or you can turn it off if you like.

Operating instructions will be included with the unit.

Yup. It better be zero.

used any?

Except you slowed down the electrons on their way through
your appliances (made them do work). Speed them back up (do
work on them) and you'll see a zero bill except for the
minimum line-maintenance fees, of course.

It has changed a _little_ in some places. The switch was from 240v, with
tighter +/- margins, to 230v, with larger margins. The margin allowed, was
large enough, to include a normally set up 240v, or 220v system in a
country. However some areas of the network were outside these margins, and
have gradually been replaced, and on new areas, the tap change voltages,
are now designed to be closer to 230v, than 240v.
If you have incoming power monitoring equipment, you will find that
typically the voltage has fallen by a couple of volts over the last few
years.

Best Wishes

The mains here has come down a little, it used to average around 247 before
"harmonisation", it's now averages 243. During sh**/shave/shower time it
drops marginally under 240, and again during evening meal time.

That's a pretty solid legal argument. I'll probably incorporate it
somewhere into my Writ.

AH, BUT, how do _they_ know for sure _they_ are getting back the same electrons _they_ sent out?
Do the little suckers have tatoos?
Maybe I have a generator (such as my $500 combination treadmill/generator. I run damn fast) that's feeding back MY OWN homemade electrons.
As soon as I think of a way to identify my personal electrons I'm going to send them a bill. And since my electrons are of higher quality (not to mention organic) I'll charge more for them.

Whether we wanted Bush or Kerry, makes no difference. We got who we got.
Time to put those differences aside and hope for the best. All the moaning
and groaning, bitching and complaining isn't going to change the facts of
who has claimed victory. This country needs some major remodeling and
someone - anyone - needs to roll up their sleeves and get to work.
Actually, the majority of the politicians are crooked as hell. Most of them
have been in too long.

As to the foreigners who wrote our fellow citizens trying to persuade them
who to vote for, I say BUTT OUT. You have enough trouble running your own
country - small as it is. We have gotten along 200+ years without your
input, and we'll get along another 200+ years. Yes, we have our squabbles,
and yes we may bitch and disagree... but dammit, when the shit hits the fan
as in 9/11, we get together and kick ass. WE left jolly ole England once -
we thought it was for good. Then we had to go back to save your asses. So,
kick back and relax and drink your tea. You mind the store there, we'll mind
ours - here.

IF you disagree with me, then do me and the rest of my fellow citizens a
favor........ don't ask for any more welfare.
One more thing - you hate Bush? Well... your Prime Minister is chiming along
with him, so let's see how well you do in your own election! PRACTICE WHAT
YOU PREACH. We'll be across the pond watching - not that we give a damned.
You won't see us writing any letters to your people to persuade them to vote
for anyone in particular. WE're #1, all else - pick a number. But don't
stand so close, we can't stand the stench.

TBA

(TRUE BLOODED AMERICAN)

LOL! OK, ;-)

Delrin rod, Acrylic pipe/rod, PVC plumbing (not to be used for VHF), is key to the project.

There are many pubs out there on making variable capacitors, the ARRL Radio Amateur's Handbook, and lots on the net. This is important, because the body is basically the same - rods, two square blocks of plexi or other insulator material, feed through hardware.

The difference though, is you can use three threaded rods, but one must be smooth. Use a 1/8" brass hobby rod, threaded at the ends. You'll need a die & handle for that.

Wind your rod. 14AWG house wiring is what I used. wind a spiral with one end ending in a near-complete circle. This will be the "common" connection.

Your slider. Use a nylon bushing. This will be needed for friction. Electrical will be less important, because there will be no potential difference. Make a brass tab and dremel a notch in one end that'll fit the diameter of the wire used. The end of the tab should be bent back on itself a bit, to reduce binding. The other end of the tab, drill a small hole and attach to the nylon bushing with a 2-56 screw. Solder a flexible wire, litz, or that stuff used on speaker cones, from the tab to the end of the slider rod.

Your common. Same tab, only soldered directly to one of the other, probably threaded rods. The tab will touch the end of the roller you made the complete circle of wire.

Assembly. Same hardware for making a varicap, only instead of where the plates go, place your roller.

I should really make a drawing ;-)

Well, if this isn't a gag, then you have to pay because of the
effort required to shove all those electrons down the electron tube
to your house, and scoop them all up from the ground when they
come back.

The guy that operates the crank refuses to work for free.

Cheers!
Rich

This is not true either. You are charged for THE ENERGY REQUIRED TO
SHOVE THEM THROUGH YOUR SYSTEM.

The electrons are incidental, very much like the push rod that connects
the piston to the crankshaft.

Cheers!
Rich

Well, yeah, except that it's so simple to "explain away" by just saying that you're not paying for the electrons themselves that are just passing through, but the energy required to get them to do that passage.

They've got the motor, you've got the wagon. The electrons are just a medium, conceptually indistinguishable from the way a V-belt transfers energy.

I've said this in other FUs kinda ad nauseam, tonight. :-)

Thanks,
Rich

Is it any wonder that the rest of the world thinks of america as it does with bigots like you who
have their heads so far up their arse you cant tell the shit from the shit.
Thank goodness it may not be true.
Bush is no more representative of all Americans than Blair is of Brits.
They got elected, but that is politics.
Most politicians couldn't give a straight answer if it had a flagpole to hold it upright.
Marco

Thank you Gentlemen for all your replies.

I would be interested to know more about doing such a coil by myself as I could access to machines. Nevertheless I don't have any idea about a personal design. So if one could drop it in my e-mail box. Specially a copy of the QEX issue of January 2003. Unfortunately my QEX subscription started in october 2003. My e-mail box is my "call sign + @skynet.be".

Thanks and regards.

73 de ON5MJ - Jacques.

I guess I'm missing the logic of your argument. Why do you think you owe them for the positive half of the cycle and they owe you for the negative half cycle? Both half cycles produce (positive) work in your appliances, so you owe for both halves of the cycles. I guess that if you feel that strongly about the issue, you can always disconnect from the mains and make your own power from solar panels, wind generators, methane digesters, fuel cells, wood and steam, gas generator, etc. I'm not sure where in the world you are, but here in the USA, you are not FORCED into being served by any electric utility. A great place to start on that issue is http://www.homepower.com and order their magazine. Tons of people use "renewable" energy sources to power their homes either in full or in part.

I happen to work for a power utility and we are installing methane digesters on large farms in the area. Cow poop in equals electricity and fertilizer out.

YOU can install your own digester, and if, for example, you live in a farming community with a good supply of manure, you could form an electric cooperative whereby the MEMBERS of the coop drop off manure, you shovel it into the digester, methane is produced through decomposition, collect the gas, use it to fire a generator set and sell or provide the electricity to the members...By the way, it takes about 750 cows to provide enough manure to have a continuous supply of gas to fire the generators and produce approximately 750 KW of power...enough to supply the needs for approximately 50 homes at full load in each house (240 Volts at 60 Amps). If each house is only using say 5 KW at any instance, 150 homes could be served from the above noted digester. You can form your own power plant if you desire (at least here in the USA)...

Sounds like Einstein's theory of relativity. It all depends on the point of reference.

The power company could be providing YOU the courtesy of having electrons piled up at your open switch and your appliances are just waiting for you to close the switch so that they can do some kind of work to give meaning to their lives.

>AH, BUT, how do _they_ know for sure _they_ are getting back the same
>electrons _they_ sent out?

They read the meter, which only lets out (with one exception, see
below) the electrons they send it when you turn on a switch and turn
them loose.

>Do the little suckers have tatoos?

"Tattoos". No, but they don't have to, since the power company knows
that since they were the only ones sending out the electrons, the ones
they get back must have been theirs in the first place. (Note the
exception below.)

>Maybe I have a generator (such as my $500 combination treadmill/generator. I
>run damn fast) that's feeding back MY OWN homemade electrons.
>As soon as I think of a way to identify my personal electrons I'm going to
>send them a bill. And since my electrons are of higher quality (not to
>mention organic) I'll charge more for them.

That's already being done in lots of places, but the buying price for
imported electrons is fixed by law (usually) so you don't get to
arbitrarily determine how much you charge for your electrons if you
want to sell them to the electric company. What you do is to run your
electrons through the meter backwards, and then when the electric
company reads your meter they'll know where the surplus of electrons
(or fuel) at their facility came from and they'll pay you for them and
then sell them to someone else.

> 73, Leon

Difficult indeed!

I worked at Barker & Williamson during the early 60s when they were
still making these things. First of all, you have to go out and
located silver plated bare wire for the coils. Then you're going to
have to machine yourself a precision roller that also needs to be
silver plated, and a silver plated rod to carry the roller with as
little lateral friction as possible.

The balance is comparatively simple, if you have a source for G7 or
G10 material to fabricate the frame, and are comfortable in machining
fiberglass-epoxy laminates to a reasonable degree of precision. (B&W
of course used custom molded and glazed ceramics, not laminated
fiberblass, but that is simply a nit!

I personally wouldn't want to even attempt it. Far cheaper to buy a surplus variable inductor.

Harry C.

It was the Brits who "TRIED" to persuade "OUR" election. Stay the hell out of OUR business. We don't need your bull shit induced in our country. We told you that 200 years ago.

Bigots? Who the F#$K saved their asses????? (your's if in fact you are Brit) Huh?? You pansies sure can't save your own asses. You can't deny history! It is U.S. - the American Tax Payers who shell out our money to save the f&%king world, because the candy asses can't do it alone. IF "WE" didn't put all the "foreign" welfare bums on our welfare roles, we'd be far better off. OUR people wouldn't be hurting as they are. OUR seniors go without medicines and food cause we're too busy paying for the rest of the dead beats around the world.

IF it weren't for U.S.- you'd be speaking something other than English or whatever the hell you mutter. If it weren't for US, the Brits might STILL be in ruins. "WE" shelled out BILLIONS to rebuild their sorry asses and have YET to be repaid in full. WE have a right to be pissed. It is OUR money spent and OUR men and women who die for your sorry asses. It was said once, about 20 years ago, if the European countries would repay us for rebuilding them, our Social Security coffers would be well off til about the year 2075 or so. That is a LOT of money.

THE ONLY thing I agree with you on and you me, is the politicians being liars.

Quite frankly, I don't give a shit what the candy asses think of U.S. - They sure know where to turn for money! What they DO think, is we're a god damned Bank - better yet, one big "Grant" never to be repaid.. That shit should stop immediately. I can guaran-goddamn-tee you, we'd be hated for sure..... You can't say we wouldn't. WE give - give - give, and get kicked in the teeth every damned time. Every damned country we've helped has tried to screw us up the ass. THAT IS THE TRUTH. Iraq, Afghanistan, and I can go on. ALL got some of our money, now we are fighting them. FRANCE - stabbed us in the back. England, well, I'm sure in due time - they will too. We're TOO damned trusting and too damned liberal with our tax dollars when it comes to other countries. As long as I am a tax payer, I have every god damned right to be pissed off.

IF you have to ask, then you don't belong in the U.S. if in fact you do live here. IF you are a resident, then you're a traitor.
THIS country pays dearly in money and lives for the rest of the candy ass world.

Paranoid? Nah, I don't think so.... We have no reason to fear. Some of us may die, but we'll take a hell of a lot more of the enemy with us. I will agree with Bush on one thing. You're either with us or against us. Truer words could never be spoken.
But the fact is, MOST who claim to "be" with us, stab us in the back. As I said in a previous post, we're TOO trusting.
WE need to just do it alone and be done with it. WE're doing most of it alone anyway.

Whether I like Bush or not, isn't even the question. I'm sick of our country being walked on by others - others who we have helped and continue to help - then you candy asses have the nerve to talk about us? YEAH RIGHT! Stuff it up your ass. Bush is our leader - right or wrong. It is the bigger picture I look at. ALL our women and children's safety. The economy of our country faltering while we act as saviors to the world. OUR men dying because the candy asses aren't man or woman enough to stand up on their own two feet.

Yeah, maybe we are stupid--- for giving a shit about the rest of the world. Guilty as charged. Our sentence is handed down daily in deaths and dollars.

Paul's in the UK, but I think you've hit on a terrific idea in that if
he installed a digester outfitted with a toilet seat he could,
single-assedly, supply electricity (_and_ fertilizer, God knows,) for
most of Europe!^)

Hi,
Does anybody have a copy of "The Pegasus Book of Radio Experiments" by
F.G.Rayer that thue would be willing to sell?

Best Regards,

Nick

Hey, I was going to give the surplus hot air suggestion a try, but I
couldn't afford to run a pipeline all the way to Austin. ;->

You're probably right. Sigh... I still think I'm a dumbass sucker,
though. But at least no one seems to agree with me on that.

Big deal. All they've got to do is pull some carbon rods out of a pile
of radio-active crap and the job's done. How hard can that be?

3659. EG&G OCXO Spec's?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-14 23:33:08 UTC
From: "Leland C. Scott" <kc8ldo@arrl.net>
Message-ID: <R8Cdndgslqy5dgrcRVn-sw@comcast.com>
Source record: 22143

I have a couple of NOS EG&G oscillator modules I picked up real cheap, but no data. The modules look new and never used. Can anybody supply electrical and or performance data for this OCXO module?

Name plate data for one module:

EG&G Frequency Products, Inc
Cincinnati, Ohio

P/N: 626718-1
Freq: 5.000000 MHz
S/N: 63989-3
Model: H174
Date: 9133

If you do please send it to me by using "my-call-sign"@arrl.net or just post it on the NG.

Regards;

3660. Re: Looking for roller inductors

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-15 00:46:55 UTC
From: Ken Scharf <wa2mzeNOTTHIS@bellsouth.net>
Message-ID: <i_Sld.14085$jE2.9738@bignews4.bellsouth.net>
Source record: 22144

The biggest problem with a home brew rotor inductor
is going to be a low resistance contact with no
dead spots as the coil is rotated.

For an antenna tuner, we can make do with a tapped
coil and a small variable inductance in series with
the tapped coil to "fill in" the gaps between the taps.
To do this I would use a 'blast from the past', a variometer.
This consists of two coils, one fixed and one rotating inside
the fixed coil. If both are the same inductance (so the outer
one is would with wider spacing than the inner) when they are
in "series aiding" the total inductance will be the sum, plus
the mutal inductance. When they are series opposing, the total
inductance will approace zero. (over simplifcation).
Variometers have NO moving contacts so they are easier to build
than rotary coils. They can't be made as large in inductance
without avoiding other problems (large distributed capacitance),
but a small variometer in series with a multitapped coil is a
good compromise.

If your antenna tuner has two caps then you can often just use the
tapped inductor, with no rotary at all (says Tim, who's antenna tuner
has a rotary inductor...).

2 Watt FM Stereo Broadcast 88-108 MHz LCD Digital PLL Transmitter

Auction ends in 1 hour!

Ebay item #: 5730774971

Ends Nov-14-04 19:13:56 PST

My Ebay Feedback rating is 100% positive.

Ebay user ID: righteous-jude

Direct link:

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&category=4675&item=5730774971

This transmitter is an assembled and tested unit -- not a kit.

This FM Stereo transmitter is well-known among Ebayer's as being the best transmitter you can get for the money. You'd have to buy a commercial brand FM exciter (such as a Harris) to exceed the specs of this unit. On virtually all FM receivers you would not hear the difference.

You could hook up and transmit any sound source you want, such as:

1. The sound output directly from your computer (to play MP3's) using iTunes or any software you like.

2. Directly connect an iPod, CD Player, tape deck, an XM Satellite Radio etc. right to the transmitter.

3. Use a professional mixer board if you want to "DJ" live. A decent Behringer UB802 Mixer is only $49. Then you could mix and cross fade between two different stereo sources LIVE. Add a decent microphone ($19) so you can talk and people won't know you aren't a commercial station until they realize "Hey, why aren't there any advertisements?"

This FM transmitter is DIGITAL (not analog) and can equal the sound of commercial FM stations. It can transmit anywhere between 88-108 MHz. It outperforms ANY of the Ramsey or other so-called "kit" transmitters, including the "export" version of the FM-100B which Ramsey sells for $429.99 - which is WAY more than the cost of the transmitter I'm selling.

Depending on the quality of the antenna you connect to it* (see "NOTE" section below) and how high up in the air it is, it is possible to get about a 1.5 mile range using a simple homemade outdoor wire antenna, or over 5 miles of range with a $70 pre-made omni directional roof-mounted antenna.

This transmitter has a filtered RF output which means it puts out a clean signal. RF filtering is important to avoid interfering with other FM stations, or if you intend to add an RF Power Amplifier* to increase your range. Most other low cost FM transmitters have bad RF harmonic suppression which means they cause a lot of interference to TV's and radios in your neighborhood, which will attract attention to you from people like Cable TV technicians (something you definitely want to avoid).

For the technical stuff:

This transmitter uses 16-bit Direct Digital Synthesis (D.D.S.) modulation of PLL carrier using 16-Bit digital oversampling, just like the Harris and other Digital-type professional FM Exciters do.

This transmitter is a new design and DOES NOT use the "BA" or "Rohm" analog chip - ANYWHERE IN IT AT ALL. Which is a good thing.

The heart of the transmitting circuit uses a DSC (Digital Signal Controller). This is a 16 bit DSP microcontroller with on-chip Flash, RAM, A/Ds, PWM, and 200k of EEPROM.

D.D.S. modulation technology is used to generate and modulate the carrier signal of higher quality FM Broadcast exciters.

I can't reveal the complete design, but the heart of it uses a Cypress Semiconductor DSC.

A Motorola-designed Class-A linear wide-band amp module (originally designed for use by cable-company operators as line transmission amplifiers) results in virtually no unwanted spurious harmonic output, high reliability and EXTREME SWR ruggedness. The RF output of this transmitter will withstand greater than a 30:1 SWR mismatch without failure. Which means if your antenna shorts-out or dies, this transmitter will not fail.

The transmitter has a LCD digital display, an on-screen menu system with two buttons for adjusting operating parameters such as transmitting frequency, modulation level, MPX pilot level, etc. It can transmit in mono or stereo and runs on 12-24 volts DC input.

Here are the specifications for this transmitter (from the manufacturer):

Transmission Frequency: Adjustable between 87-108 MHz
Tuning Steps: 10 kHz
RF Power Output*: Typ 1Watt @ 13V or 2 Watts @ 24V
Spurious RF Emissions: Better than -45 dB ref. to carrier
Frequency Stability: PLL Typ +/-1KHz
SWR Ruggedness: Withstands 30:1 SWR mismatch
RF Output Connector: BNC type
Audio Input Sensitivity: 0.8V rms for +/- 75 KHz deviation
Signal To Noise Ratio: 60 dBu
Frequency Response: Flat from 20 Hz to 15 KHz
Stereo Separation: >40 dB
Pre-emphasis: 75 uS (standard FCC spec for U.S. FM radio)
Audio Distortion: Better than 0.2 % THD

Audio Input Connectors: RCA Phono Jacks
Power Jack: Coaxial type, 5.5mm O.D. 2.1mm I.D. center positive
DC Power Input: 12 to 24 Vdc Regulated 600mA

I won't list all the details here, you can learn them all by going to http://www.Ebay.com and entering item # 5730774971 using Ebay's "Search" Feature.

This item will be available for only 1 more hour:
auction ends Nov-14-04 19:13:56 PST

"Yeah, OK all that stuff is great, but how can I tell how good this transmitter will sound before I buy it?"

The Ebay auction listing gives instructions for downloading MP3 sound files of recordings made of the FM transmitter signal received live, on-the-air. You can judge for yourself.

** Please read the section of the auction explaining how I got the best sound quality from this transmitter, and how the live off-the-air MP3 recordings were made. **

*NOTE: If you are concerned about gov't compliance regarding the unlicensed use of this transmitter within the United States (or elsewhere), an "RF Attenuator" (also known as a T-pad) may be attached to the output of this transmitter. This is a simple screw-on device which will reduce the transmitter's RF output power to a level within the guidelines mandated by the country in which you intend to operate this transmitter. Guidelines vary from country to country. In the U.S. unlicensed operation of this transmitter is permitted under the mandate of the FCC's guidelines for "Unlicensed Operation of Part 15 Transmitters", provided you do not exceed certain restrictions such as RF output level or type of antenna. Compliance guidelines may be viewed at:

www.fcc.gov/mb/audio/lowpwr.html

I went on a quest.

Sheesh. OK, you're showing the same mentality by your blockheadedness
about the electricity.

I came up with "neocon" because of election hangover, and probably
confused names because of the frenzy.

So, sorry if I got the wrong guy, but upon reviewing the thread,
if it ain't a gag that you're really dragging out, in which case,
either congratulations or you should be ashamed of yourself, but
if not, then you're one of the most stubborn, blockheaded people
I've ever encountered, republican _or_ democrat!

Does this clear things up a bit?

Thanks,
Rich

Source record: 22049

Is there a source of ANZAC component data on the web?

I'm looking specifically for data on the THV-50 2-port hybrid (power divider) and the CD-50-4 4-port hybrid.

Maybe I can explain. Paul is basically a moron when it comes to
electronics - real slow on the uptake, engineering math challenged,
Jerry's kid. He probably OP'd this thread without thinking of the
work required to move those f*cking electrons - the more you move in
a given time, the more power you consume. Goes back to mechanics and
horsepower. OTOH, he *is* a f*cking troll, basically, so you might
just ignore him. I sometimes look at the responses to him because
you never know when someone's gonna blast him (like you're getting
close to doing) and sometimes (not this time) it's good for a
chuckle. 'specially after a few good Long Islands :)

Not really. I'm neither republican nor democrat. I'm a Britlander so
those terms are inapplicable. My politics are actually quite
middle-of-the-road and moderate, actually. Not that we should be
discussing such things here, anyway.

3672. Miller Vernier Panel Dial Available

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-15 18:00:09 UTC
From: Al <no.spam@wanted.com>
Message-ID: <no.spam-601F2D.12572115112004@news.verizon.net>
Source record: 22056

I recently picked up a used Miller vernier panel dial assembly, P/N 10035. It is about 6.5 by 7.75 inches. It has five scales on it labeled A,B,C,D and E as well as a 0-100 scale at the bottom. It takes a little over 6 turns of the knob to move the slider from 0 to 100.

If you're interested, send email to afjay@earthlink.net. I can then send you some jpgs showing its condition. You can have it for the cost of shipping and the price is whatever it's worth to you.

Al

Not sure, but somehwere it has to be stated that electric company MUST
provide an escape route for electrons they supllied to customers,
otherwise they will blow up your house in an eyeblink (assume you try
to steal their electrons). That's the only reason for the bill.

What kind of insulation is on the headphone wires? I've seen many that use enameled copper, and it's very easy to 'solder' a couple of enameled wires together such that they physically stick together but don't make electrical contact with one another. This may be what's happening in your case.

But if you need to install the tuner outdoors
remote controled via servo motors, guess how
long that sliding tap will give good contact?
At least sealed relays can be used for the
tap switch.

Well, I admit I got kinda confused when I went to google groups
and each time I spotted him chiming in on the election frenzy,
he was on the opposite side from the last time. ;-)

Cheers!
Rich

Would that be the slide rule string dial, or the cog belt varity?

FOLLOW-UP

My 40meter dipole, which I just put up, hangs over a corner of my garage. About 5ft above the roof. I suppose that's close enough to trip GFCI's. And it's only about 15ft above ground. But it works great!
Someday I might have to put up some sort of vertical.
My old 20meter dipole, which is a little more out of the way, works fine. Doesn't trip any of the GFCI's.
I put a homemade air balun on the 40M yesterday. Didn't seem to make any diff.
Tripping GFCI's in the garage is mostly just a nusiance. I can put up with it. Although I have a 24hr timer on one circuit. But I wonder if it affects the neighbors' GFCI's. I don't think I'll ask them.

Some Anzac parts are now made by Tyco. But for most
of them, you have to have a paper Anzac catalog (I have
carefully saved mine). Same thing with the old
Watkins-Johnson company that made mixers. Save
the paper catalog if you still have it.

Thanks to everyone who pointed that out. The THV-50 is a current product on the website of M/A-COM, who bought ANZAC but were in turn gobbled up by Tyco.

The CD-50-4 remains a mystery, so far (but definitely not a typo - I'm looking at it right now).

>But for most
>of them, you have to have a paper Anzac catalog (I have

I normally do save them, but threw out the ANZAC one about 15 years ago because I didn't have any of their parts... at that time.

Sadly, the whole catalog collection in the loft is now under threat, as we prepare for relocation next year. The very last to go will be the 1986 HP catalog, because that has most of my testgear in it!

If it's out-a-doors and remotely controlled, then
there's no reason for it to be in contact with the
atmosphere.

A large plastic sealable freezer container is what you want -
very easy to seal the wires with hot-melt plastic glue.

3696. Amateur Radio Elmers Resource Directory

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-16 14:08:05 UTC
From: "Paul W. Schleck" <pschleck@novia.net>
Message-ID: <419a091d$0$9373$45beb828@newscene.com>
Source record: 22080
Cross-posted to:
rec.radio.amateur.misc,rec.radio.amateur.antenna,rec.radio.amateur.digital.misc,rec.radio.amateur.homebrew,rec.radio.info

The Amateur Radio Elmers Resource Directory, a list of experts, mentors, and gurus for amateur radio on the Internet, went on indefinite hiatus on June 1, 2000 after just over 9 years of service. This decision was not forced upon me by anyone for any particular legal or technical reason. Rather, I decided to retire from maintenance to focus on other personal and professional interests and obligations.

I also felt that I had taken this project to the limit of my expertise and spare time in terms of format, visibility, automation of maintenance, effective recruiting, and even good Web design. It's clear that the Internet had changed greatly over the 9 years that the Directory had been in existence. The Directory had evolved from a flat text file edited on a VAX running VMS to a well-featured Web site. However, in that time, much better amateur radio-related web sites had emerged (including QRZ, Ham Radio Online, and ARRL) that make my site rather simplistic by comparison. Also, it's clear that many more enhancements would be required to make the Directory more maintainable and secure. One requirement that the Directory did not address is reasonably shielding the Elmers from having their E-mail addresses harvested for junk-mail distribution lists.

I want to emphasize that I do believe that using the Internet, the Usenet Newsgroups, and the World-Wide Web to bring Elmers and amateurs requiring assistance together continues to be worthwhile. Because of this, I would consider a highly-qualified and motivated volunteer to take it over immediately. The Directory consisted of a moderate number of large text files, scripts, and other configuration files. It's neatly arranged, and can probably be easily transplanted to another Unix/Linux environment. I would also be willing to assist with importing the data into a database such as mySQL. To help transition this project to another maintainer, I had prepared a maintainer's guide, available on request. The ideal candidate will be a motivated self-starter and self-teacher possessing several years of experience in:

- Unix/Linux
- C or Java
- HTML
- Perl or Python
- Procmail
- Version control systems such as SCCS, RCS, CVS, etc.

(this also implies that you have the above tools installed in your environment)

preferably on or more of the following:

- SQL
- PHP
- CSS

and have approximately 4-6 hours of spare time per month for maintenance. A track history of successfully completing projects would be a firm requirement. Please note that hosting sites are already available. Offers to host the project, but not maintain it, are not being sought at this time.

Familiarity with news.answers formatting conventions and the auto-faq FAQ Management and Posting Package would be a plus. Concrete proposals for enhancing the Directory to be a top-10 amateur-radio-related Web site would also be desirable. I would also consider the Directory being incorporated into an existing commercial amateur-radio-related Web site as long as the essential non-commercial character of the Directory was maintained.

If you feel that you possess the interest, motivation, and immediate, hit-the-ground-running, skill set to do this, please send your statement of interest and any proposals you wish to make regarding your plans for future enhancements to elmers-request@novia.net.

I would like to thank all of the volunteer Elmers, as well as courteous users of the Directory, for making this service a success, as well as an enjoyable experience for me over 9 years.

Good day Guy & Gals I live in Windsor Ontario Canada just across the river from Detroit, so I have quite a few american friends, you could say that this problem has nothing to do with me, but living in close proximity as many Canadians do, we are joined at the hip at President Bush might say even if he might not want to acknowledge it? we are friends and neighbours our economy is tied together big time, myself I dont like his foreign policy, we will need each other sometime or other no matter what anybody says. We all have the right to protect our country, just insulting each other is why we have our problems, talk is cheap but can achieve much. all the best Dave.

Dave,

You make a valid point and I agree with prejudice. The following remarks are not intended directly at you, but to sort of address the issues a bit more.

MANY Americans disagree with Bush getting back in. In saying that, I'm not admitting to having voted or not - for him.
Some of his policies suck. What I do agree with, is his tone of "You're either with us or against us". But as I said, many of those who "claim" to be with us, end up stabbing us in the back.

Being our closest neighbor, yes... things could be "better" between the U.S. and Canada. They should be. While I may not agree with "everything" in principle, things could be much better.

Those who called us Stupid Americans, are A. Traitors from within or B. "so called" friends.

Though Bush won, Kerry could have had he had enough votes. So too could have Nader or any of the others in their individual parties. England or any other country has no reason whatsoever to try to sway our voting, nor do we of theirs or anyone else's. The voting machine has spoken - right or wrong, and we all must deal with it. LOTS of work in the U.S. alone needs done. There are domestic issues which need attended to. BUSH is capable of doing it, IF he chooses to do so.

Let's face it, the majority of all politicians are as crooked as a cork screw. It's always been that way and always will - regardless what country it is. It is up to the people to attempt change using the process as established. The other problem is, not many "qualified" or well rounded

candidates are there to choose from. Special Interest groups get their hands in it, and so on. IT SUCKS. But, we must deal with it. These last few elections it has gotten worse instead of better. They used to "Debate" policies, not get into the crap they've recently been doing. I don't give a shit if the man in the white house got a speeding ticket 20 years ago. I want to know what he's going to do NOW to give a helping hand to this country's needs. Actually, I'd like to see "Foreign" policy forgotten about for a while. Let the others do their thing whilest we take care of our own - for a change. So long as no one is fixing to attack us, I could give a shit less what they're doing. Live and let live!

"I" am not the one who started this thread of insults. But I'll be damned if I'll sit back as an American to have some half wit from another country cut down on us. Whether I like Bush or not, doesn't matter. HE IS THE PRESIDENT - as such, I have to respect that. BUT in the larger picture, I do my own part to defend their safety. Yes, we all have our disagreements and so on, what country doesn't? But we deal with it. We don't need outsiders casting their opinions when they aren't in any better position to do so. You can hate our government all you want, many of us do as well in some respects - be it the local, state or federal - especially if things aren't going our way... but to start a campaign of insults of our intelligence - man... that's biting a dog in the ass and sooner or later that dog will turn and bite back.

HOW DARE any one from another country call US - STUPID. IF you don't like it, come here and try to become a citizen, then you'll have every right to bitch and a chance to perhaps change things - at least with your vote since you must be an American {born here} to become President. You don't hear us whining about the Canadian/English or other governments do you? NO. Because WE DO NOT CARE. WE have enough problems here to take care of. SO, unless one is willing to put up - then SHUT UP. THAT is meant for the loud mouth who started this all and any of his supporters.. The jock straps that they are. The "government" gets involved more with the other countries, while most of us could care less. We're too busy eeking out our own existence. My opinion is to leave them all do their own thing, stay out of their business - even with foreign aid, which I'd love to see cut off forever. BUT - if they come here to attack or we hear of plans of an imminent attack on US - kick their asses and make them non returnable - period. Defend our borders and to hell with the rest. Let the other countries take care of their own problems - in every respect. This country does a hell of a lot for the world, we don't need the bull shit from the peons of society to dictate to us. Go back to your momma and grab a titty bottle, cause we're not listening.

I've said it once, I'll say it again.. IF you don't like the Americans... FINE - kindly remove yourselves from our Welfare roles. Don't cry wolf at every shadow - to have us come running to help. Put a pair of trousers on instead of your panties, step up to the plate and be a man - make a go of your own country and it's economy, and quit sponging off of U.S.

Dave
Absolutely agree, but some poster on here have their heads so stuck up b** that they cannot see the
reality of world life.
The world does not revolve around America (or any other country for that matter), and the sooner
they realise that no-one owes "them" a living, the soon that perhaps the whole world can live in
peace.
Well we can dream can't we ??

Ah, the ass hole farts again..... Excuse me, the rest of the world DOES revolve around US, with their revolving requests for our tax dollars and military aid. YOU need to realize - ASS HOLE, if it weren't for the US, YOU would be speaking German or Russian. DICK WAD..... READ YOUR F*&KING HISTORY BOOKS. Oooppps, I told you that before, so it's obvious you CAN'T read.

Problem is, you talk of dreaming, YOU ARE DREAMING. You never woke up to the reality that you speak of. Wake up and smell the tea.....

3706. New program - Coax Choke

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-16 23:05:33 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <cne13t$3a9$1@hercules.btinternet.com>
Source record: 22090

```
New program SELFRES2.exe
-------------------------------------
Input data :

Length and diameter of solenoid.
Number of turns.
Conductor diameter
Length of line in which the coil is inserted.
Testing frequency.

Output data :

Coil self-capacitance.
Coil self-resonant frequency.
Choke impedance vs frequency.
Insertion loss of choke in dB.

Performance is based on a choke wound with coaxial cable of the same type as
the transmission transmission line in which it is inserted. Conductor
diameter is that of the coax outer. It behaves a single wire. Coax inner
diameter is of no consequence.

Choke insertion loss is a measure of the reduction in power radiated from
the feedline. But, despite the attention it attracts, actual power radiated
from the feedline WITH the choke will never be known because the power
radiated WITHOUT the choke is indeterminate.

SELFRES2 is 51 K-bytes. Download from website below in a few seconds. It is
not zipped-up and will run immediately.

3707. Montreal Fox Question

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-17 00:57:06 UTC
From: Tim Wescott <tim@wescottnospamdesign.com>
Message-ID: <10pl8em3q0ulp25@corp.supernews.com>
Source record: 22091

Anybody on the list who has experience with the Montreal Fox? I just got one to the point where I can start entering call signs, and it's acting very strange -- I can enter some letters & numbers, but others won't go, and if I try my callsign it just pukes.

Is this a known problem, or do I have a unique issue here?

Thanks in advance.

The cog belt type is identified by the square tubing that the cog belt
rides in. Other kind is totally internal. Cog belt kind of drive is
a little rare, a Millen experiment if you will.

I got caught on this one too. It wasn't headphones but a int/ext temp gauge.
The external line broke and I stripped the wires and resoldered them. No
output.
On closer inspection, the two wires were actually very small shielded
wires (I'm not too good in the eyesight department these days) and I'd
stripped the outer and the inner insulation in one go.
Have a closer look at your headphone wire.

Can someone with experience with the part tell me if there are
sufficient differences between the PIC 16F84 and the 16F84A to cause
problems during EEPROM write? I have purchased the "A" part for a
circuit (and software) that calls out the plain-jane version. I'm
having problems (described below) that are either the thing locking up
in mid-write or are _really weird_.

I suggest you go right to the horses's mouth: the 84->84A migration
guide is at http://ww1.microchip.com/downloads/en/DeviceDoc/30072b.pdf

It looks to me as if there are some voltage, and timing differences
involving access to the EEPROM. Dunno whether that's the cause of
your lockups, though.

http://ww1.microchip.com/downloads/en/DeviceDoc/80083b.pdf is the
16F84A errata document.

Source record: 22004

Thanks for the suggestions, Steve. I've updated the file to incorporate them. The new file is at http://eznec.com/Amateur/RMS_Power.pdf.

During recent trips to Powell's Technical Bookstore and the library, I looked through a number of books about electrical circuits which are oriented toward hobbyists and technicians (that is, ones lacking the math of a college level circuits text). I'm glad to say I didn't find any which were plainly wrong about average and RMS power (like the Joe Carr book quoted earlier here). But what nearly all of them do is to introduce RMS voltage and current pretty early on in the text, and explain that the RMS values of voltage and current are important because they represent equivalent heating values (which is correct). From then on, they simply use E and I with the assumption that they represent RMS values of voltage and current. At some point, they introduce the equation P = E * I or, in the more advanced ones, E * I * cos(phase angle), and maybe at that point mention that P is the equivalent heating power (which is also correct). What I didn't see in any of them was the fact that the product of the RMS values of E and I is the *average*, and *not* the RMS value of P. It's easy to understand, then, why a lot of people, like a number of the folks who posted comments and questions here, naturally (and incorrectly) assume that the product of Erms and Irms is RMS power. The books simply don't contain the information you'd need in order to discover that Erms * Irms = Pavg. Hopefully the paper posted by Rosenbaum and the one I did will help fill the void.

You could do that, but again, if you have enough other adjustments you
can probably make the fine adjustments on the caps.

My first antenna tuner, which I used for several months, was just an
L-network with a tapped coil (with an alligator clip) and a variable
cap. By reversing the direction of the thing and dinking around it
always worked for me -- and since it was on an open piece of aluminum I
could hear, smell and see when I was putting too much RF into it for the
little broadcast tuning cap!

Hi Roy,

there does seem to be an unsettling amount of misinformation, errors
and poor explanations in the majority of text books I've encountered,
I'm sorry to say. No wonder there's such a huge amount of confusion
surrounding these aspects of our hobby. :-(

>
>

In "1970 product summary" I found under Hybrids 0-180 degrees:
CD-50 (no -4)
Frequency 80-1000 MHz (note Octave Coverage)
Max. loss 0.5dB
Max.Unbalance 2 degrees 0.3 dB
Max. SWR 1.5:1
Min. Isolation 25 dB
Power rating (Watts) 50

Some help I think. But you need a catalogue from mid/late 70 or
very early 80:th. (Its not in the 1984 cat.)
Fig. 4 could be the connector type, but in this 1970 cat the
connecor is B , N, S, T (BNC N SMA TNC).

Thank you, Per-ï¿½ke!

It is indeed a 1/180deg hybrid coupler. At last, I think I understand the little drawing on the label.

The module is a square box with a port on each side. If you inject a signal into any port, it seems there will be a null at the port on the opposite side of the module; but only if the impedances connected to the other two ports are equal. So one use could be as a return loss bridge.

Alternatively, with a load terminating the opposite port, the two side ports can be used as either a 0deg or a 180deg hybrid power divider with good isolation between the output ports (and that 50W power rating looks interesting).

The frequency range on the label says 175-350MHz, so maybe the "-4" indicates an option.

Well, all that gives me something to go on. Next stop will be to sweep it in the various connection modes, to see what loss and isolation it really does have... and of course how well it performs at 144MHz and 432MHz.

Once again, thank you all very much!

P=I^2R, so which direction the current is flowing is irrelevant, as the
squaring removes any negatives, and R is always positive.

Would be interesting if you could get a true -R though! (not like a tunnel
diode, which just has a small region where increasing V decreases I, but
it's still positive)

3728. M/A COM Gunn Oscillator Info ?

I am looking for info (frequency, power out, current) on a M/A COM Gunn Oscillator with WR42 waveguide output. The part number (barely visible) appears to be MA86819, though the middle digit in particular could be mistaken. Date code appears to be from 1977. It is mechanically tuned (only) and is marked +6.6V DC. Has anyone got any data for this one ?

73,
Steve VE3SMA

In my case I can't have a look into the tuner or handle alligator clips as the tuner must be remotable and outdoors. The shack will be soon located in the cellar and it will not be possible to pass the ladder line through the house. A coax would be rather acceptable indoors. So I am looking for a good solution for the inductors: roller inductors, tapped inductors, tapped inductors with small variable serie capacitors. Driven by servos or stepper motors. Maybe I don't need a fine tuning of the inductors because of the main variable capacitor could be enough.

It's a well-known problem. The slotted rings that hold
the controls to the front of the radio loosen up over
time and pushing on the knobs flexes the pots until they
break loose.

I believe later production has a glop of hot-melt
glue on each pot to mechanically stabilize it with
the PCB.

I don't have a schematic but I can't help but think
the control head is toast based on my experience with
one FT-8100R.

Dana

I spent years perfecting a bar magnet with only a North pole. (Monopolar) I set it down on a table for a moment and it promptly took off for Antarctica. I haven't seen it since.

I've been making them with only South poles for the last year, but have them all tied down. I'm going to release them on December 24 and give Santa a big surprise.

3734. RF Power Measurement at 900MHZ

Source record: 22019

Hi,
I have 20 900MHZ ISM band modules and I would like to measure RF power. I have a a Tektronix 2712 Spectrum Analyzer and some attenuators(BNC) and RG 58 coax. Unfortunately I do not have an SMA connection on the antenna port. there are pads for the antenna that I could fit an SMA to but I none of the ones I can find fit quite right because of physical interference with the RF shield.

I tried soldering the RG 58 coax to the signal and ground pads but the signal was not visible at the spectrum analyzer. I know RG 58 is lossy but the Belden Coax calculator said I should lose about 20% of the power at 1 mwatt.

Any thoughts or suggestions regarding coupling this signal (100 to 500mW) to a power measurement would be greatly appreciated.

Thanks,
Ed V.

For those of us on the western side of the pond can
you describe these magazines. Looks like a UK version
of Popular Electronics, perhaps with more of a computer
slant. Wonder if any of the projects would be of
interest (parts available?) to us yanks.
Any ideas of shipment cost this way?
Thanks!

I will! Particularly since when _I_ build a system with DSP it
generally works exactly as I've predicted it will. If I'm deceived,
then so is God -- are you saying that God is deceived by how DSP works?

Winding toriod coils around a doughnut is about on par
with what one Heathkit builder did when he ran out
of insulating spaggati tubing....he used macroni!
(TRUE STORY as told by some Heathkit repair center employees)

No, the same guy has posted to all kinds of newsgroups, and they
are indeed nonsense posts, albeit with a slight slant towards
the newsgroup. But the giveaway, apart from recognizing the name
after a few times, is that they are all posted to the newsgroup and
can.sun-stroke

People are saying he is trying to score points, and the "points" accumulate
when people reply to the message, and it lands in can.sun-stroke Note
that I took that other newsgroup out, so he will never see it over there.

3747. Magnet Wire Stripper Gel Substitute?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-21 00:26:14 UTC
From: averyfineman@aol.com
Message-ID: <20041120192614.06260.00000109@mb-m26.aol.com>
Source record: 22031

Many years ago GC Electronics of Rockford, Illinois, supplied a fast-acting enamel stripping gel under the trade name of "Strip-X." It would "lift" the enamel within a minute or two, was rather pungent and no doubt (in today's ultra-health-conscious world) toxic.

When my last bottle ran dry, I got some paint stripper from a neighbor that worked nearly as well. Alax, neighbor moved away and I never recorded the name of the commercial paint stripper.

Anyone have any suggestions for a chemical stripper gel or solution? Will PCB "stripper" gel work on enamel-covered magnet wire? [expensive stuff for a tiny bottle of that]

Mechanical means of enamel stripping are the pits and I can't justify the cost of a commercial stripper machine such as the Eraser. Solution solutions welcomed.

Stripping magnet wire? You mean like after making coils and wanting to
solder them to something? Why bother? Just put a blob of solder on
your iron's tip and put the end of the magnet wire into the solder blob.
After several seconds, the insulation will melt off and the wire end
will be tinned with solder and ready for install!

I usually just take a piece of 120-400 grit sandpaper, fold it in half
and pull the wire through it. Several passes usually is enough.

3752. Re: RF Power Measurement at 900MHZ

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-21 04:33:22 UTC
From: Andrey <a8421@intergate.bc.ca>
Message-ID: <10q06865kju152c@corp.supernews.com>
Source record: 22036

Interesting...

What exactly do you want to measure? Power output from the Module? Or power received by the module?

In an case, here are some check-ups you may find useful.

1. Check if your SpectrumAnalyzer "sees" 900 MHz signals. Take 75mm of bare wire, attach it to the input of Spectrum Analizer - to central connector. Orient the wire vertically. This will be your quarter-wave length antenna. You should see activity in the band - signals, on different channels, of different modulations.

I do not know where you are located, but if it is urban environment there should be some activity on 900MHz ISM Band, and below the band you will see cellular activity etc.

You will see signals with amplitude -40 to -80 dBm.

2. If you want to check if your modules transmit, bring it close to antenna - you will not need even antenna on your modules to see the signal from them. Again, I do not know what is your output power, but if it +10 - +20 dBm, you will see plenty of signal when the module is close to your antenna.

3. Have in mind, simply powering up the module typically does not make it transmit. There is usually separate line that turns Tx 'on' and more.

I hope this helps,

Andrey

Was anybody keeping count of the number of postings to this thread BEFORE it became personal and acrimonious?
Seems like some posters lack the necessary sense of humour? They seem to hate anythingthey say be challenged?
Then, as a reaction they descend in childish name calling and attempts at derision. Shame!

Sticking to the subject. "Why electricity (for our antique radios of course) is/is not free". Well, hmm! The tube heaters use full wave, but what about those pulses of one way rectified half wave AC for the B+? (Primarily in non transformer radios!). Intended pun; non power transformer radios don't have a primary! :-)

Personally I'd like to 'rectify'? my high electricity cost!
Our consumption is recorded by a 60 cycle analog AC meter on the outside of my house, which is owned by the power company and read and billed monthly. Maybe I could get those positive half cycles and then not 'return' the negative ones, as someone has already suggested, and reduce electricity consumption that way? Joking of course :-) What good would half cycles be to respectable AC operated equipment?

So anybody got any other 'practical' ideas, in addition to burning my non electric wood stove during the winter, to reducing my electrical heating cost?

Our domestic electricity presently costs about 9 cents Canadian per kilowatt hour. That's roughly 7 cents US and roughly 4 UK New Pence, per unit/kilowatt hour. This part of Canada is a pretty small and somewhat widespread market. I believe that in Ontario in central Canada, a much larger population and population density, it is, or has been, due to political pressure following a botched attempt to privatize the electrical system? substantially less than that at around 5 cents; even though much of the energy is generated, by hydro power, in Labrador in this particular part of Canada!

Thinking about it.

Which means running ones 1MW anti-gravity machine only costs a trivial
$70 per hour. Cheap at twice the price.

<< I am in need of a manual for a Heath HW-100. >>

Charlie-

In case you are still looking, you might expand your search to include the HW-101, SB-100, SB-101 and SB-102.

The main difference between these models is the VFO module. I think each is unique. If you need information about the rest of the radio, there is very little difference. For example, one might use dial cord to couple shafts that rotate together, while another might use an O-Ring as a belt.

I've been watching this thread for a couple of days, and I gotta
believe it's just a troll. But while we're at it, why not ask the same
question about your water bill.

After all, they're just charging you for water, most of which just
gets returned, with "interest."

;-)

3765. New Kennedy assassination audio!

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-22 09:52:47 UTC
From: brad.johnson@turner.com
Message-ID: <af57b211.0411220152.3b5f7e35@posting.google.com>
Source record: 21949

I am looking for TV and radio broadcasts of the JFK and RFK assassinations. I am particularly interested in audio recordings of such broadcasts made by amateurs.

If you personally tape-recorded or obtained -- or know of anyone else who tape-recorded or obtained -- any television or radio broadcasts concerning one or both of the two Kennedy assassinations in 1963 and 1968, please contact me.

Whether it's a network or local broadcast, whether the sound recording of that broadcast is of good quality or poor quality, whether it was recorded in a major market or in a minor market, I want to know about it.

I'm a collector, so if you have any of this or know about someone else who does... please email me or have them email me at:

bkj333@aol.com

Thanks!

w8zr is a member of premium-rx and IIRC the project was mentioned in a favorable light by Greg (The list owner) shortly before the article was published.

There is a discussion group on the w8zr site where quite a few people have left comments and questions resulting from building and using the multicoupler.

I did have a reel to reel of the 1968 RFK events in LA. We were testing new
audio recording equipment (late night, of course) and were letting it run
off one of the TV feeds.
Unfortunately, it was lost in 1970s.

Often times, many news sources play at least "tidbits" of those audio files.
I'm sure a documentary will be on soon which will play many parts of those
files.

Speaking of this event, did you hear - some sick bastard(s) in the UK
created a game about this, called "Kill the President"?
And they're supposed to be our friends? YEAH RIGHT..... Those
bastards ought to be found and executed.

NO ONE and I DO MEAN - NO ONE should buy this game to support their sick
minds. ANY STORES that stock this "game" should be boycotted.

This isn't as funny as it sounds. I was renting a room from a guy once,
and he was complaining that when he waters his lawn, they add the
gallonage (or whatever the word is) to his sewer bill, the theory
being that most of the water to a house goes out the city sewer.

I suggested rain barrels, but he didn't think that was very funny, either.

Cheers!
Rich

Hey,

Thanks for the note.

So, like, this reel-to-reel definitely is gone forever, right? Not even the remotest chance you might possibly have it tucked away somewhere and have just forgotten where it is? (Sigh) I would dearly love to hear your reel if there's any chance in a 1,000 it might simply be misplaced somewhere.

I'm working on a very interesting project involving the RFK assassination and one of the things I'm doing is piecing together amateur and professional audio, video and film from that night (I've gathered up a good bit of material thus far and there's been some truly amazing results so far).

If you might happen to know of anybody else who has such material, I would love to get in touch.

Again, thanks so much for your note. And, just out of curiosity, do you happen to remember which TV network it was that you were taping with the reel-to-reel that night? Which local market were in at the time?

Very best wishes!

Brad

I am afraid not. It was either the NBC (WGEM) or CBS (KHQA) affiliate for
the Hannibal/Quincy market (one of the smallest TV markets in the US).

My wastewater charge is directly tied to my incoming water consumption
metering. I get a slight advantage, however, in that I go to the pub
every night, drink 10 pints of beer and don't need the lavatory until
I get home. :P

Hi Andrey,
thanks for the info. It turned out that the module that was
not showing any signal on the spectrum analyzer was dead. I got
another one and soldered in a RG 58 cable and hooked it to my spectrum
analyzer through a 20dbm attenuator. Its working fine.

We have a similar system here (San Diego County), but they compute the
"sewer" charge by using the lowest three winter billing periods over the
last four years. I guess it is an attempt to measure water consumption at a
time of year when there is less lawn sprinkling.

Source record: 21967

hello...

my old but trusty hp141t (1.2ghz) appears to have developed a fault/out of calibration??

it all works but now there is a spurious reading (peak) about 6.5mhz down from the fundamental peak..about 55db down..its always there when a signal is present (but not of course when no input.)
It's defiantly the analyser as I have tried different tx sources and its always present..
sniffing rf via bird 43 attenuator..

Any ideas??

When you switch in an extra 10 db of attenuation at the input, does
the spur drop 10 db as well as the wanted signal drop 10 db?
If spur drops more then IM is being generated in the analyzer from
overload possibly.

Yes. I enjoy building. I usually build something, test it out, and go to the
next project.
>
> Q#2 - How does the "Assembly" of the Kit go ?

The kit is for an intermediate builder. It went well because the assembly is
well
documented. The is lots of mechanical assembly on the front and rear panels
because
of the number of switches, LED's and connectors.
>
> Q#3 - Does the "Finished" Kit perform well enough so that it is
> 'worth' the Money and Time to built it ?

It does a good job, and the construction is solid but the video amplifier
chip
is noisier than passive splitters. I have lots of receivers in the workshop
and
having the ability to drive 8 receivers is a godsend, however. I also
listen to low
frequency signals (below 500khz) and it does a good job in this region. For
lf reception I replaced the 0.1uf coupling capacitors with 1.0uf units.
>
> Q#4 - Are there 'cheaper' Lower Cost Ready-Made alternatives
> to this "Kit" ?

The purpose of the switches is to enable each receiver by controlling the
mute.
If you don't need to control the mute of you receivers and don't need a
preamp
you might look a some passive splitters from minicircuits labs. The passive
splitters
will have loss, however. A 4 way splitter has 6db loss; an 8 way splitter
9db, so you would
need a preamp.

question now bout these things!

if i built a 5 port device, what would be the insertion loss (so i can calculate the power rating of the resistors)? would it be 3dB or 7dB (the signals aren't in phase or anything, in fact they're different frequencies).

thanks again!

dr. x

3790. Re: Metal film resistors?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-24 19:12:43 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <10q9n9cj2m72523@corp.supernews.com>
Source record: 21974

They're not wirewound. They consist of a thin film of metal deposited on a ceramic tube, which is helically cut to leave a conductor in a spiral pattern. A wirewound resistor has a lot of inductance because it's made of many turns of wire. A metal film resistor has a very small amount of inductance by comparison -- so little that it can be ignored for most purposes.

To my knowledge, you can't use a Wilkinson divider or combiner for signals at different frequencies or phases. It'll do something, for sure, but it certainly won't function as a Wilkinson divider is intended to. You won't have port-to-port isolation, and the loss will be much greater than you'd get with simple dividing. You'll likely end up with more power going into the resistors than out the ports, so I'd size the resistors to handle the sum of all signals going in, unless you can model it with SPICE or a similar program.

Strictly speaking they are not "wire wound", but some are constructed
with the film "wound" around a substrate, thus having a lot of inductance.

If you dont't have the makers specs to tell you, the choices are to
measure the inductance or to remove the coating and see what's underneath.

3793. 5A power supply construction

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-24 19:22:57 UTC
From: Ian Liston-Smith <ian@morse-code.NO.SPAM.TODAY.fsnet.co.uk>
Message-ID: <u1n9q0l9tcr3865kqb20ohhdhphcofp9qn@4ax.com>
Source record: 21977

I'm looking to build a 3A 34V regulated linear power supply. The LM338 adjustable regulator looks just what I need, but it's upper limit is 32V.

Can a zenner be placed in the common lead somewhere as can be done to fixed regulators? I've downloaded the spec sheet, but it doesn't give specific examples of how it may be done, although says "...several hundred volts can be regulated..."

Are there other freely available regulators that will do what I want?

Many thanks,

Ian.

Several manufacturers (Caddock and some of the Vishay divisions) make
metal-film resistors which are advertised as having about the same
amount of inductance as a straight wire the same length as the
resistor body. I believe that these have the film cut into a
back-and-forth serpentine meander pattern, rather than a spiral.

Thanks for the comment on the old, tried-and-true chemical-less
way. Finishing sandpaper (dark grey abrasive surface) will work
on 36 gauge old-style enamel covered wire, also on 25 gauge
(rare, surplus from transformer winder) Teflon covered. Takes a
bit of practice and "feel" to keep from abrading too much of the
copper on the very small gauges. :-)

I use the little squares of finishing grit paper cut into four smaller
pieces, each of those folded in two. Lightly holding the fold-over,
a couple passes over the wire end is all that is needed.

On the suggestions by others -

"Soldereze" and "Thermaleze" wire would strip just by soldering
iron heating of the copper right at the cut...but still needs some
abrading after starting the melt sometimes. I've used that, but
ran out. In winding toroids by hand, that kind tends to expose
the copper in places unseen except by high magnification. For
that former the old enamel type seems to be the sturdiest (with
exception of rare and way-over-expensive Teflon-covered). In my
experience that includes Kynar covered wire-wrap type...others'

mileage may vary.

"Zip Strip" (methylene chloride) is an unknown here, including the supplier. [no supplier source posted]

The old GC "Strip-X" was the best for quick one-of-a-kind coil winding. It was definitely acidic by odor and reaction to some other materials...would have some enamel "lifting" action within ten seconds of application. Alas, my father-in-law, a polymer chemist, passed on a quarter century ago and cannot help with expert advice on this. :-(

The search for a quick stripper (of wire) goes on...perhaps aided by "inductive reasoning?" :-) Thanks again to all for replying.

They can be suitable for some RF applications. If you are thinking of the wire-ended ones up to 2-3W, they are a flat spiral of just a few turns of the metal film, on a ceramic core.

Plugging the number of turns, diameter and length into the usual formula suggests inductances of less than 0.1uH, even for the larger ones. This means they have inductive reactances rising up to about 10 ohms at 30MHz.

For example, if you wanted to use say a 47 ohm resistor as a dummy load, the SWR would be quite reasonable up to 30MHz.

However, the inductance of the higher-value resistors goes up much less rapidly then the resistance does (they use a thinner film of a more resistive material, but not a lot more turns). The inductance of a 470R metal film resistor is not a lot higher than that of a 47R. So if you were to use ten 470R resistors in parallel to make your dummy load, the inductive reactance would be divided by 10 and the SWR would be much better.

I have used multiple-paralleled 2W metal film resistors as high as 50MHz, and up to144MHz in situations where the inductance could be tuned out.

The ones I tested can also be overloaded to red heat for several seconds without significantly changing resistance when cold - unlike the cheaper carbon film resistors which burn (as carbon does), or wire-wound resistors which generally develop a hot-spot and burn out.

yes it seems to drop 10db as well...its possible to "remove" the spur by
switching in more attenuation, but doing this completly removes the 2nd/3rd
harmonics as well..which is after all what I am trying to look at..

oh the plug ins are 8552a and 8554b

Ian, I've just measured a couple of resistors bought as spares for the FL-2100Z, 33 ohm 3W metal film used as a grid stopper, and 22 ohm 3W metal oxide used on the anode, again as a suppressor, with a coil wound round it (both of the originals were carbon).

The metal film 33R measures 6.5uH and the oxide 22R measures 4.5uH on the aade.com meter. Both values (if the readings are correct) would represent a high ratio of X to R at HF frequencies...

I have quite a surplus of them, so if you wish I can send one of each in the mail for you to check on your VNA.

My guess would be 7 dB. But I would do like Roy says and model it
with Spice or whatever. Multi-way Wilknsons are just too bizarre for
my brain, though I have seen the occasional paper on the subject !

I did model a 2-way Wilkinson combiner (the microwave kind with real
transmission lines) with a single input signal and much to my (and
probably Roy's) surprise it was perfectly matched and had a 3 dB loss
from one of the two inputs to the common port.

My guess would be 7 dB. But multi-way Wilkinsons are too bizarre for
my brain ! I would do what Roy says and model it with SPICE or
whatever.

I did model a normal 2-way Wilkinson combiner with only a single input
(the microwave kind with actual transmission lines) and to my surprise
(and probably Roy's) it was perfectly matched at one frequency, had
perfect isolation at one frequency and gave a 3 dB loss from one of
the two input ports to the common port (all at the design frequency
only, of course).

Those values seem surprisingly high, so yes, please do and I will
measure them.

Based on the standard inductance formula (and there seems no reason why
that shouldn't apply in this case) it would seem to require very large
numbers of turns to achieve >1uH.

My posting was based on the ones I scraped the paint off in pre-VNA
days, so it would be useful to collect more data on typical 'coil'
dimensions and numbers of turns, together with the actual effective
inductances.

3806. DSP in receiving systems

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-11-25 13:30:58 UTC
From: David J Windisch <davidw@copper.net>
Message-ID: <41a5ded5_3@newsfeed.slurp.net>
Source record: 21990

Hi, all concerned:

Ponderings while listening to a dead 40M c-w frequency ...

What artifacts does latency in a DSP implementation cause?

I'm thinking of eg a "DSP rcvr" OOH and an "analog receiver" OTOH, both tuned to WWV, and the noticeable delay of the DSP audio from the analog audio. You know, ti-tick ti-tick instead of tick-tick-tick, and "blurred" voice announcements.

I've noticed a similar effect in add-on DSP by putting speakers at the input and at the output of the add-on device. Stereo cans make the effect downright strange.

Fast c-w QSK would seem to be a challenge, especially if latency varies with selectivity.

Makes me wonder how the commercial "DSP rigs" perform. I'm mostly satisfied with an Elecraft K2 (wish it had 200W barefoot, instead of 100W), and have fond memories of my TS-850's. Never met a commercial radio I couldn't make better ;o)

IAC, happy Thanksgiving and 73,

Dave, N3HE

> buy two identical roller inductors of about 20 to 30 ï¿½H for an antenna
> tuner.

Thnk outside the box. There is more than one way to skin the cat of variable inductance. In the old days, they configured 2 inductors next to each other, with one of them able to rotate. Varying the angle of the dangle, varied the amount of mutal coupling, effectively changing the inductance. Seems much easier to implement than rollers, which truly require serious metalworking facilities to make.

It is actually possible to inject reactance of either sign, onto a line by running a motor with an over/under-excited field current, on the line. This is used frequently on ships to correct power factor problems. Probably not facile for a desk-top transmitter.

Really old QST's are available on microfiche and on CD now, I believe. Look through the 1920's and 1930's. Those were the golden years of homebrewing. We're fortunate that we live in an epoch when that word-of-ragchew sort of alchemist knowledge is preserved in robust, widely-available media.... There's PLENTY of mathematical knowledge from the Greeks that got lost.

Large public libraries often still hold QSTs & Radio Amateur Handbooks from decades ago. Find them. Let us know what you find, let us know what you build!

Delay is inherent in most DSP systems used for filtering, because they
generally use a circular buffer for the convolution operation. It acts like
a delay line.

Tin the tips of two wires -- Smash them flat with a ball-peen hammer --
Trime the tinned leads to a wee bit less than the diameter of the
battery -- Assemble the wires and the battery by slipping some heat
shrink tubing over the whole mess -- Shrink to taste.

If you have some pices of Very Thin brass, cut two brass pieces to
a somewhat smaller diameter than the battery -- Solder each wire to
one pice of brass -- Assemble the brass pieces and the battery by
slipping some heat shrink tubing over the whole mess -- Shrink to taste.

Use hot melt glue to tack the battery in place inside the radio.

I replaced the soldered-in battery in the TS-60 by buying a battery
holder at radio shack, soldered that in, and then slipped in a $1.50
CR20xx battery.

The DSP allows you to implement a type of filter called "finite impulse
response". These have some strong advantages over the type of filters
(infinite impulse response) used in analog systems, mostly sharper
filtering for the amount of ringing, and the capability to make filters
adaptable (like adaptable notching). One price you pay, however, is
latency.

Fast QSK would be interesting, but if you were willing to go without
sidetone and perhaps hear the break request while you're keying I think

it would be doable (I wouldn't know from personal experience -- I do DSP work professionally but don't have any DSP rigs).

Probably to save money on the core -- the oven will cost a few cents
less to make, a few dollars less to buy, then you pay that all back to
the power company as your kitchen gets hot. It would also add a modicum
of voltage regulation to the thing, but I doubt that's the reason.

hi frank,

http://www.mouser.com and digikey has them.

for those with the ts-50, either the battery holder replacement with
slip in cell works fine.

The solder the wire on the cell can work but why take the chance
of heating the insides up and possible leaks later destroy the rig.

wally

It is mostly done for current limiting, which a magnetron needs because
(in DC terms) it looks like a diode connected across the power supply.
Saving size, cost and weight is also important, so the transformers are
pared right down to the bone.

They are not WIREwound, but the resistive element IS usually a helical
film that is a layer on a ceramic body.

As someone else mentioned, there are some types which are serpentine
rather than helical, but these are always special and sold as such.

Film resistors generally have fewer turns in their helix than
wirewounds, so they will have more inductance than carbon or ceramic
bulk resistors but less than wire wound resistors.

www.mouser.com. Part #639-CR2016-T, Sanyo CR2016 coin cell with tabs,
$3.75 in onesies. I imagine Digi-Key has something like this as well.

The non-tabbed versions are a fraction of the cost... I suspect the
tabbed ones are rather a specialty item.

Earlier this year I modded an Icom IC-228 which had one of these
tabbed batteries, nearing the end of its useful lifetime. I pulled a
coin-cell holder off of a defunct PC motherboard, stuck it down in a
convenient area inside the radio with double-sided foam tape (I used
the spot where a tone-squelch board would normally have gone),
jumpered it over to the existing coin-cell attachment leads, installed
an ordinary coin cell, and then clipped the tabs on the old battery
and removed it. The memory never lost power, and I can now replace
the battery again (in another 5-10 years) without having to desolder
anything.

>Ian.

I've just scanned through the data sheet
(http://www.national.com/pf/LM/LM338.html).

I can't immediately see what limits the voltage to 32V. It seems to need
a minimum of about 4V across it, and the lowest output is 1.2V. However,
there doesn't seem to be any way it knows where 0V is.

I suspect that you can do as you suggest, ie jack up the common lead to
34V minus the 1.2V reference. You will need 38V input minimum.

Maybe it potentially dies on switch-on, because the output will
momentarily be at 0V (especially if you have any capacitor between the
output and 0V). However, you'll probably get away with it! Don't forget
to connect a diode back from output to input (to kill the reverse
voltage when you switch off).

I made a 1A PSU using 7805, with the common terminal jacked with zeners
(switched in as required). It goes from 5 to 24V. I've had it for about
20 years.

Ian.

I know they purposely add leakage inductance by putting in a "shorting
bar" between the primary and secondary sides of the coil -- I don't
think allowing the core to saturate would give you any significant
current limiting on the secondary side unless you were willing to put up
with runaway current input on the primary side as your excitation
inductance went away.

Thank you Alan for your suggestions.

1. On variometers, there are subsequent questions: what about flexibility and size ? A roller coil of about 20 cm long and 10 cm in diameter, having about 45 turns has an inductance spread between 1 and 35 µH. To do the same with a variometer, with the same accuracy, the same inductance and a smooth trim what do we have to do ? I have no experience in this domain but my first impression is that the design will not be that simple. May be this could be THE solution.

2. About old QST's you are right. One of these Christmas I will ask a complete set of CD's. I also have 15 ARRL handbooks, whith "mil°sime" spread between 1945 and 2001, but not yet seen something about variometers.

OK, will post them off tomorrow night. I'll include the manufacturers info
(they were bought recently from Mouser in the US), and put two of each in
so that you can crack one of each value open and see what they're made of
;-)

Is there a standard RF input level per "S" Unit?

If so, please post the location. Thanks.

LenAnderson@ieee.org

3825. Re: potting compound

Newsgroup: rec.radio.amateur.homebrew

>remove this substance? Any ideas?

If it is relatively clear and rubbery with a slight "give" to it, a guess
is that it is probably a low out-gassing silicone potting compound
such as used in some spacecraft electronics. Those were all
one-time pottings, done after checkout and never intended to be
un-potted for any reason.

My advice is to NOT use any solvents of any kind for the simple
reason that such can get into some of the internal components
and do nasty things. Solvents have very low (almost negative)
surface tension and could penetrate any component not
hermetically sealed by metal-glass cases or all-ceramic, fired
cases. Those potting compounds of various epoxies or silicone
types were near-vacuum debubbled just before mixing their two
parts (also in the same near-vacuum) and would surround the
components but not penetrate their cases. Note: Some of those
potting materials were transparent or translucent like the common
silicone conformal coating used on old PC Boards for spacecraft.
That kind of potting material polymerized once and once "set"
was NOT usually dissolved by ANY solvents.

You MIGHT be able to use a soldering iron to dig into the potting
material to loosen most of it, but that creates some (unknown
effect) smelly vapors. In the end, the parts would have to be
salvaged by mechanical means such as carefully picking away
the stuff by a model knife (old reliable X-Acto type and its
cousins with lots of spare blades for replacement). That's a
very labor-intensive task...like two working days to remove the
translucent potting compound around a multi-stage voltage
multiplier block for the designer's evaluation after full environment
testing (EOS Spacecraft Fab Lab back in the 1960s). It may not
be worth it for a hobbyist. That's an individual call.

Jet Propulsion Laboratory in Pasadena, CA, had, and presumably
still has an excellent polymer laboratory and "rules" for NASA on
polymers for spacecraft. Somebody there could give better
advice (information is free, unclassified, but speaks in chemistry
terms, not requested much) on potting removal methods. That
isn't "casting plastic" (acrylic) one can buy at the Michael's craft

store chain.

Emerson and Cuming are specialists on potting and coating
compounds for electronics (also wideband RF absorber material).
You might inquire to them about this material and see what they
have to say. Also anyone that makes silicone rubber compounds
for potting or just do a search for "silicone potting" (not just the
word "potting" or there are too many hits on the results).

There is no "standard". You will often see it mentioned as 6 db of power per S-unit. At one time 50 microvolts into the receiver was S-9 and you went down 6 db of power per S-unit from there. I doubt that any receiver will follow that so called "standard".

The rule voor 50 V = S9 does still exists, this is voor HF, @50 Ohm input impedance at receiver.
"They" (radioamateurs) use another rule for VHF.
It's in the software MultiCalc, Google will find the adres, it's for free.
Official or not, if everyone use this rule then it is a standard for me.
Greetings Bas.

I find that most of them seem to sort of follow the rule that 4uV is S9, 3dB down is each S-Point, that's for VHF/UHF.

There is an IARU recommendation, which originated in Region1
(Europe/Africa) and I believe has been adopted by IARU world-wide.

The Region 1 recommendation is:
http://www.algonet.se/~k-jarl/ssa/IARU/smeter.html
Google should also bring up the full technical paper behind this, and
probably the current IARU recommendation. ISTR there's something on the
ARRL website too.

The 1990 Region 1 recommendation simply states that:

STANDARDISATION OF S-METER READINGS
1. One S-unit corresponds to a signal level difference of 6 dB,

2. On the bands below 30 MHz a meter deviation of S-9 corresponds to an
available power of -73 dBm from a continuous wave signal generator
connected to the receiver input terminals,

3. On the bands above 144 MHz this available power shall be -93 dBm,

4. The metering system shall be based on quasi-peak detection with an
attack time of 10 msec +/- 2 msec and a decay time constant of at least
500 msec.

IARU functions very much like an
Entmoot...only...not...quite...so...hoom...hasty. In 2004, they are just
starting to think about the gap between 30MHz and 144MHz:
http://home.hccnet.nl/a.dogterom/Vienna04/vie04_19_Chair.rtf

But all the other comments about S-meters are true as well: that no
S-meter actually conforms to this recommendation; that it makes no
practical difference; and that hardly anyone cares.

There's a very good web page with lots of practical measurements, at:
http://www.seed-solutions.com/gregordy/Amateur%20Radio/Experimentation/SM
eterBlues.htm

Source record: 21864

If you're wondering if S-meters are calibrated to some standard, the answer is that they're not. S-meters simply read the AGC voltage, which is only approximately logarithmic. Therefore, the number of dB per S unit typically varies from one part of the scale to another. For example, the S-meter in my Icom 730, on 40 meters, preamp off, varies from 1.3 to 4.0 dB per S-unit depending on where on the scale you are. The "10 dB" increments over S-9 vary from 5.6 to 13.5 dB. Receiver manufacturers are free to make the sensitivity whatever they want, and seldom exceed about 5 dB per S-unit, because users complain that the meter is too "Scotch" (insensitive) if they do.

There is a tendency for receivers to be calibrated to about 50 microvolts at one point on the meter, S-9, and there's often a calibration adjustment for this.

Any "standard" is useless at best and misleading at worst, because it bears no relation to what S-meters really read.

On HF there is no need for an S-meter standard because it seems to be
the rule to give report 59. If you don't you soon have a bad
reputation of giving wrong reports

I installed an MC3356 log detector and calibrated it for S9 = 50uV.
For about 15 years there has never been any signal of S9+30dB, most
reports should be around 539....579, but again you logging problems,
because everybody expect 599 and some log programs don't include the
reports, they are supposed to be 599

My homebrew solid state receiver (see QRZ.COM) uses 5 dB per S-unit. S9 corresponds to -73 dBm available power, which is 100 microvolts open-circuit from a 50 ohm sig gen, or 50 microvolts into a 50 ohm load. Available power and open-circuit voltage are used because the input inpedance of the receiver is not guaranteed to be 50 ohms. I use 5 dB per S unit because it compresses the scale a little and it also agrees more closely with the intuitive listening test measure that I have used for many years. The upper end of the scale is 30 dB above S9, which is -43 dBm, a very strong signal. Signals stronger than S9+30 dB I don't bother to measure. At S1 the signal level is -73 - 40 = -113 dBm. Signals weaker than that S1 I don't try to quantify.

My receiver has a low noise RF preamp with 8 dB of gain that I use on the 12 and 10 meter bands, when those bands are quiet. This makes the S meter less accurate but I don't worry about that. To get an S meter reading I turn off the preamp briefly.

My receiver has a custom made, computer printed scale using a calibrated sig gen, and there are two trimpot adjustments, one for the low end and one for the high end. This circuit uses voltage regulated opamps. The S meter dynamics are adjusted using RC time constants.

My S meter is accurate within +/- 2 dB from 160 M to 10 M, because the receiver is designed for this accuracy. Because of the IF and RF circuit design, the scale calibration is fairly correct and reliable, as I mentioned.

My receiver also has a 20 dB antenna input attenuator that can be switched
in from the front panel. This extends the upper signal range to S9 + 50 dB.
I use it very rarely.

the LM338 is, after all, a voltage reference, error amplifier and pass element with current limiting -- you can raise the adjust pin above ground with a zener to make a higher voltage regulator -- but you have to remember to bias the zener since the adjust pin current may not be enough to do the trick.

The LM338 is comparatively expensive. If you have to regulate 40V at 5 amps, an LM337 HV and a husky PNP will do the job cheaper, or you can just use a zener and a PNP for a "super-zener", albeit with limited performance.

Here's how I did it for an amplifier which I had to completely take apart and strip down:

A signal doesn't have to be S9 to be heard 5 by 9.
I would usually tell the guy on the other end what
the S meter read, and also how readable he was.
When the band is quiet QRN wise, I could honestly
give a 59 report to someone hardly moving the meter.
OTOH with heavy QRM+QRN someone could be pumping
30db over and still be a rough copy.

Then you are still passing out wrong signal reports. The first one would be
something like 5 x 2 or 5 x 3 and the second one would be 2 x 9 or 3 x 9.

The first number is how well you can understand what is being said and the
second is how strong the signal is.

A "pulse forming network" is a simple LC lumped approximation to a short circuited transmission line. A voltage step is applied to it, and after the round trip time of the "transmission line", the input drops back to zero. The resulting pulse is applied as the supply voltage to a radar transmitting tube such as a klystron or magnetron, which produces an RF output pulse of that width.

Because a PFN limits you to a fixed pulse width, I doubt they're used much any more -- there are lots of advantages in being able to vary the pulse width.

I worked on heavy ground radar on the DEW line in the mid '60s, where this technology was used. On the radar I worked on the most(*), a pulse of several kV was applied to a PFN by connecting it to a power supply with a thyratron. The thyratron was extinguished when the trailing edge of the pulse occurred. The pulse width was a few microseconds. This was applied to the primary of an oil-filled transformer which the magnatron plugged directly into. The transformer stepped the pulse voltage up by ten times and applied it to the cathode of the magnatron, which then oscillated for the duration. The applied power during the time of the pulse was over 5 MW, giving 5 MW output power. The pulse repitition rate was between 2 and 3 ms, so the average power was in the several kW range, and the range of the radar was several hundred miles. The insides of the PFN would physically constrict when forming a pulse, so it produced a fairly loud audible buzz of 400 Hz or so when the radar was operating.

(*) See http://www.radarpages.co.uk/mob/rotor/fps6.htm or http://www.radomes.org/museum/equip/fps-6.html. I don't think the ebay PFN came from this exact same model of radar, but it's from one of comparable size and vintage.

Anyone who did a radar course at RAF Locking in the late
50's or early 60's should remember the FPS-6 height finder
alongside one of the training blocks as the "Nodding Horror"
since such was its local name.

The PFN in that eBay ad is of British manufacture. You
can tell that from the '99' in the NATO part number and
the colour scheme is typical also.

Cheers - Joe

3842. Re: S-Meter Calibration Standards?

Newsgroup: rec.radio.amateur.homebrew

There has been a de-facto HF standard for 60 years.

The USA military first used it in specifications of radio equipment when placing contracts with manufacturers around the end of WW2. There may have been some restrictions on publicity at the time.

The Standard is 6 dB per S-unit and 50 micro-volts into 50 ohms at S=9.

Therefore an S-meter is essentially a power or wattmeter.

The Standard is quite logically derived.

The 6 dB fits in very nicely between a typical receiver's internal noise level (S=0) and a typical receiver's signal overload point (S=9+30 or 40 dB).

S=9 is about half way up the scale which is linear in dB's, or S-units, from one end to the other.

There's nothing wrong with the standard. If your S-meter reads incorrectly then don't blame the standard - re-calibrate the meter. If you can't re-calibrate it blame the poor quality of the meter.

I have two relatively modern commercial transceivers plus two home-brewed transceivers. Their S-meters are accurate enough for the intended purpose. What more should I expect?

Roger that, and I've heard all kinds of "599" reports on-air, too. :-)

In the project I have on-going, this receiver's S-Meter (there mainly
for nostalgia purposes and because I've gotten a few old-style
microammeters that I can use) will read the average carrier power
(integrated to a time-constant yet to be settled on) at the AM
detector using a half of a quad op-amp integrator. That same
detector provides the AGC control line with appropriate DC offset
for the MC1349 gain blocks, but with (maybe) different integration
time-constants. As for the RF input to the antenna connector,
that is known within +/- 2 db down to -130 dbm by separate
calibration of my HP 608 or 606 signal generator. When
completed, this particular receiver S-Meter will be as accurate,
with a custom scale plate, as that signal generator output will
allow.

Of course, to fit the "convention" of those gratuitous "599" reports,
I could borrow from the auto industry's cheapie "gas gauge" which
has a single bulb showing "low gas" on the dashboard...using an
LED driven by an op-amp integrator-comparator for high-tech.
The indicator would show "I got signal" or "I got noise" to fit... :-)

Thanks, Bill. I'm doing essentially the same...and expect the overall
receiver response to the flat within +/- 1 db within an octave and a
half tuning range. Accuracy of the S-Meter is only as good as the
RF level accuracy of the calibrating RF source but that's another
task and I have confidence in that. But, I have to start someplace
and that is why I asked about a "standard." I know that the U.S.
military didn't bother with any receiver S-Meter calibration standards
since around 1980, only approximate differential signal strength
readings if there was an indicator at all.

Thanks, Ian, and thanks to all others responding. A plus to Reg
Edwards for mentioning the U.S. military receiver specs which
I was hunting around for but could not find. :-(

Reason for asking is that I'm going to make a meter scale for a
little receiver a-building, using (nobody blanch, please) MS
Paint from a scanner (accurate 1:1) digitization of the removed
meter scale plate. I've done that with a normal-expanded scale
meter on a 120 W variable autotransformer box used on the
bench. MS Paint will do color in 256-color mode for a better
appearance. An inkjet printout on heavy photo paper stock
results in a fine-grain scale sturdy enough to replace the stock
plate in a little 2 1/2" microammeter.

Note: That works only on the old-style meters with removeable
scale plates (screw mounting type). Newer snap-together plastic
case types aren't recommended for that.

That method started on wondering how accurate an ordinary
scanner was...solved by scanning a 6-inch metal scale, printing
it, then comparing the real scale to the printout. By eyeball it
was dead-on! :-) I've done that for drill guides on PC board
stock used for both circuit boards and small enclosures since
and find it very time-economical. Machine shop accurate it isn't
but then my home shop drill locations were never that accurate
using scribe marks on "dye-chem" blue lacquer painted on
aluminum. :-) [rubber cement holds the paper printout on the
work, removes easily afterwards]

Most people appear to be fatally attempting to use, in reverse, their favourite S-meter as a means of calibrating the Standard. No wonder we have so many different standards around.

The difficulties in making an accurate power meter lie solely in the very wide range of power levels encountered.

0 to S-9 corresponds to 9 times 6 dB = 54 dB.

S-9 to +40 dB corresponds to 40 dB.

Making a very high total range of 94 dB for a power meter.

That explains why S-9 usually appears just over half way up the scale.

For a range of 94 dB it is not beyond modern technology to make a linear dB scale out of it. The limitation is manufacturing cost. But who wants to pay an extra hundred dollars to replace a receiver they are already happy with.

Of course, if you MUST have an accurate S-meter, the cheap way is to obtain a blank meter scale, a fine-nibbed pen, a bottle of black ink, a signal generator, and a 0-100 dB switched attenuator. You will proudly end up with a work of art and a beautifully cramped scale at the bottom end. But when done it's as accurate as you like!

Hint: There's no need to obtain a new blank scale if the existing scale can just be turned over to its white side. Such small divergencies can make restful breaks in between investigations of skin depths at 1 to 10 Hz of the ocean bottom of transatlantic submarine cables.

Places like Battery Mart can weld tabs to any battery that they carry.
You could also just install a battery holder from a dead computer
motherboard. I have a couple here if you need one for the price of
postage.

Just to tidy up.

And I've been through this before but I'm just a bloody foreigner who favours French wine.

The S-meter is a power meter.

The standard receiver input impedance is 50 ohms.

That's why you get a conjugal match when you switch the transmit tuner from transmit to receive but you don't get such a match when you switch back.

The standard, HF, 50 microvolts at S-9 into 50 ohms corresponds to 50 pico-watts which is an inconvenient quantity to refer to in signal strength reports. Hence the popular S-units.

S-9 requires a standard 50-ohm signal generator, set to a standard open-circuit 100 micro-volts, to be connected to the receiver. Receiver manufacturers in their maintenance manuals usually prescibe this at the non-descript frequency of 7 MHz.

The internal thermal and other noise level of a typical receiver with an input stage consisting of a balanced modulator (the first frequency changer), referred to the receiver's input terminals, with a receiver SSB bandwidth of 4 KHz, is of the order of 60 dB below S-9. That is a little less than S-zero on the meter. A signal level of the same order as the noise takes the meter to S-zero.

A signal level of S-9 plus 40 dB, or 40 dB above 50 pico-watts, corresponds to a signal input voltage of 50 micro-volts times 100 which equals 5 milli-volts. At which point a good receiver begins to overload and suffers from non-linear intermod products.

Hence we have a meter range of 54 + 40 = 94 dB as displayed on a typical meter.

All this fits in very nicely with the recognised S-meter Calibration Standard.

(I do hope I have not made an arithmetical error. But I'm sure you Americans get the general idea nevertheless.)

They are operated in a resonant system, unlike an ordinary HV transformer.

Leon

We have seen a dozen or so posters indicate that S9=50uv

Nowadays, very few rigs have analog meters. Instead, they have a computer
that can take that AGC voltage and display it however the computer decides.

In the Icom calibration procedure for the 706, there are three calibration
points known by the computer ... S0 (0 uv), S9 (50 uv), and S9+60 (50 mv).
The calibration procedure sets these three with known inputs, and presumably
the computer interpolates from there. That really isn't a bad calibration,
and I'd be surprised if other modern rigs were much different.

Now it is quite likely that there is some dependence on the AGC voltage with
frequency, but again, in a modern rig that should be manageable.

What isn't so constant, of course, is the antenna. The voltage at the
receiver could range over several orders of magnitude for the same signal
depending on the antenna. So in terms of providing input to the sender, the
S meter reading is still of limited usefulness, even if we all had
calibrated radios and agreed that S9=50uv.

If you mean the actual strenth of the signal in uv at the antenna,
then you are correct. If you mean the strength of the signal in your
EARS that's another story. One is an actual measurement, the other
is subjective. (How would you measure signal strength if you
were using a receiver without an s meter, such as an old SW3?)

Thanks, Leon. Can you expand a bit? Are you suggesting that one or
both windings have some sort of parallel/series/real/parasitic
capacitance to bring the winding into resonance and if so, what's the
purpose behind it?

I don't mean a thing. If you take some time and review the RS(T) system you would see how it works. The first number is how well you understand what is being said from just catching a few words to understanding everything. The second is the strength of the signal. As the SW3 does not have an AVC system you may be able to judge the strength by how far up you have to turn the volume control for a certain loudness in your ears.

The secondary and primary are resonant with each other.

The self-capacitance of the secondary is all that is required.
(Compare with early Xtal sets that had an FGL, but
no tuning capacitor (or condenser for those days) in evidence.

defining the proper time-constant for ssb is another problem. My
activity has mainly been VHF/UHF cw and ssb, and working a few HF
contests on cw. Found that reporting and operational style is somewhat
different on HF and VHF. While the normal report on HF is 59 or 599,
it varies much more on VHF, and 519 report is not rare on VHF -
particularly if the OP has no experience from HF.
My favourite report is 559, because it is easy to send using elbug,
and it makes some fun, particularly when everybody expects to receive
a 599 report, so the opposite OP must make a note in his log that the
report wasn't the usual type, and somebody most likely may loose score

Now we are getting to my bands of operating. Instead of the RS(T) type of reports grid squares are usually used on VHF. That eliminates the bogus 599 type of reports and while probably never used it will give a rough check to see if you actually copied the call correct as the grids can be compaired to the other stations that worked the same call
.

S-meters are nothing else but power (input) meters.

Amateurs and meter manufacturers long ago learned, that when giving signal strength reports, it is more convenient to refer to meter indications in terms of S-units rather than micro-watts or nano-watts.

At HF, when the meter reads S-9 the power entering the receiver is 50 pico-watts. There's a slight complication above S-9 when the meter scale changes to decibels above S-9.

When the reading is S-9 plus 40 dB the meter is actually indicating about S-16. It's just a matter of scale graduations and printing.

The S-meter does NOT measure or even indicate field strength. It indicates nothing except that an increase in meter reading corresponds to an increase in field strength. Which may be nice to know but by how much of an increase is anybody's guess.

Measured field strength depends on the type of antenna, its efficiency, ground losses, etc. It is possible, of course, to calculate field strength in the vicinity of the antenna from S-meter readings provided the antenna, its directivity, transmission line, tuner and ground characteristics are all known numerically. Which in the amateur situation they are seldom not! Or even in the professional situation.

You've all got one. To repeat - the S-meter is a power (input) meter.

> apart?
==========

Paul, I've never seen a Tesla coil or even recollect seeing a photo of one. But I can imagine.

They are a means of generating very high voltages at relatively low radio frequencies.

Low radio frequencies to minimise RF radiation losses.

The coil is quite an ordinary, single-layer, solenoid, close-wound or relatively close wound in the form of a helix. Grounded at the lower end. Open circuit at the top, high-voltage end.

It is coupled to the RF generator via a few turns link winding at the bottom end.

Or the generator may be tapped into the bottom few turns.

The working frequency is that at which the coil is self-resonant with its own distributed self-capacitance.

The generator, by virtue of the number of turns on the coil and the number of the turns on the link coupling, is impedance-matched to the Q of the coil such that all the generator power is dissipated in the coil's RF resistance. This, of course, corresponds to maximum voltage at the top of the coil.

The situation is identical to a short HF helical antenna without a whip on the top, operating say in the 160 or 80 metre band - but without the radiation loss.

The radiation loss in the Tesla is low because its operating frequency is low. Most of the power being dissipated in the wire resistance.

The theory is very simple. The coil inductance with its self-capacitance must resonate at the working frequency. The coil Q must be very high and the wire resistance must be low to generate a very high voltage.

Many turns of wire are needed to resonate at LF but the wire diameter must be large enough to have a low resistance. Hence the larger the physical size of the coil the higher is the attainable voltage.

The few number of turns on the link (or tap) coupling is calculable but is better determined by experiment. One will always end up by pruning to match to a particular generator impedance for maximum Tesla voltage.

The coil's inductance is easily calculated from well known formlae. The coil's self-capacitance is more complicated. But what is really required is the resonant frequency. Or it can be found by experiment. (Which is what Tesla must have done.)

It so happens that my program SOLNOID3 will calculate the isolated self-resonant frequency of a solenoidal coil from its dimensions. For Tesla coils dimensions will be in metres and inductances of 10's of milli-henrys.

The practical design problem is insulation between adjacent coil turns. And of course the driving power. Having never seen one my instinct guides me towards a coil length to diameter ratio of 15-to-1.

Have you any intentions of making one?

Reg, G4FGQ

>p.
Primary coil is a tank circuit (parallel LC usually) resonant with
the secondary coil. The secondary is usually placed inside the
primary coil.

While the primary is a parallel resonant circuit with a coil and
capacitor, the secondary is just a coil and series resonant, or a coil
with a large metallic body at the end to serve as a capacitor (spheres
and toroids are used to minimize corona loss)

A few turns of relatively large diameter wire or tubing in the primary
and a lot of turns in the secondary. 6:400 turns ratio is typical
enough for small systems, but that ratio isn't carved in stone.

The primary is wound as a helix or spiral, the secondary is wound on a
tube form, much longer than the diameter as a rule. Tuning the
primary to the secondary's resonant frequency is achieved via tapping
the primary coil with a movable tap.

Tesla or Oudin coils can easily produce hundreds of thousands of
volts. Lots of different forms and techniques are used to maximize
the output voltage - that's where it gets interesting.

The theory is simple - but building good coils takes experience.

They can be driven with high voltage transformers and spark gaps (the
most common technique) or vacuum tubes or solid state devices.

They are simple to build, good for high voltage experiments, producing
ozone, great visual effects, X rays, produce some RFI, etc..

There is a Tesla coil mailing list on the net that is very good. If
you want to build one (and I recommend it) they can be an invaluable
resource. http://www.pupman.com/ Lot of links to working tesla coils
and construction ideas.

Lindsay Publications www.lindsaybks.com is another source of books on the topic (among others). Lindsay reprints books published at the turn of the century (that would be the 1900's) on technology. It is fascinating reading about tesla and induction coil construction - and you can still build the stuff today with more modern materials. They did have a paper catalog of their books in print - may still have it.

I built a few coils and a 1KW induction coil to drive them.

Of course, one must never forget Dr. Spottiswoode's 'Great induction coil';
first exhibited at a meeting of the Royal Institution held 13th of April
1877.
The wound secondary was 0.01inch diameter wire, 280 miles long. Primary was
1/2 mile of 0.1 inch wire, in // with a capacitor of 126 sheets of tin foil.
Powered fron 30 quarts of Grove's battery cells via a steam engine driven
Brass-Ebonite-Platinum interrupter, allowing 700 to 2500 impulses a second.
Generated arcs about 3.5 foot long!.
regards
john

are metal film resistors wirewound or not? I've been trying to find this one out. Someone who I know says they're not so are suitable for RF but Maplin catalog seems to say they are.

Metal film or metal oxide? There is a big difference. High ohmic values are almost always Oxide types and these are usually the continuous layer type with the occasional 'trim'. Really low value metal film are also a continuous tube or nearly so. It is the upper half of the metal film rage (100R-100k) that is spiral cut & consequently of appreciable inductance. Unfortunately, these are the values that are most needed.

I think metal film resistors are made by depositing metal vapor onto
ceramic rods in a vacuum. Then they are attached to metal end caps
with leads and either laser or abrasive engraved to set the final
resistance. Some have only a turn or two, some have more. They are a
lot less inductive than wire wound devices, and the best low
inductance versions have a serpentine pattern engraved in the film, to
keep the inductance very low.

Yes, minimal inductance, but doesn't that pattern give rise to more
parasitic capacitance?

Just a comment.

Even such a thing as a small 1/2-watt resistor has distributed R, L and C.

L and C can be calculated from physical dimensions.

A resistor can be treated as a helically-loaded transmission line in exactly the same way as a helically-loaded antenna. If the frequency is high enough the radiation resistance can be taken into account.

Just calculate the input resistance of the line with a short circuit at the other end and the job is done. The performance of dummy-load resistors can be determined in the same way.

If you (in the plural) are unable to do this then you are unworthy to call yourselves engineers. Whatever happened to your education? ;o)

I've never described myself as an engineer. I'm not one! But if I
wanted to checkout how suitable any given resistor was for a dummy
load, I'd use a network analyser.

Reg, with all due respect, I think most of the newsgroup readers
are HOBBYISTS in radio and electronics, not engineers. I happen
to be both, a design engineer for 4 decades and a hobbyist for over
5 decades of experience.

I'll just say that I disagree with your hypothesis of "helically loaded
transmission line" doesn't quite jibe with the basic question of
trying to model a film resistor. Case in point: I have four 1000
MegOhm IRC resistors having 61 "turns" of what appears to be
carbon film under the clear conformal coating, wound on about a
5/16" diameter, 5 inches long form (substrate material unknown).

For a two-port structure, the series inductance equivalent is only
about an eighth of the apparent inductance based on visual
examination and dimensions of a good conductor made with flat
wire to the same dimensions. To find out what electrons thought
of it, I hooked them up as a reactive voltage divider (analogue to
the capacitive voltage divider common to oscilloscope inputs)
and examined a square wave output versus input. Why such a
gross dissimilarity?

For one thing, the resistance helix is a DISTRIBUTED thing, not a
convenient discrete lump collection. The substrate material is
unknown, maybe something equivalent to light-colored Bakelite?
There's a further complication of the fringing capacity of each of the
61 turns to the adjacent turns or the end caps. The spacing of the

film "turns" is about twice that of the film width. That adds a capacitance component (equivalent to the distributed capacity of a solenoidal-wound inductor). The clear conformal coating may add to the "inductance" loading. Who cares? The one-evening experiment of about four decades ago showed I could make a HV voltage divider for a voltmeter at rather high input resistance up to about 16 KHz, my intent at the time. It worked.

Did I check for higher LF effects? MF? HF? No. Could that be arranged? Yes, with some slight loss of accuracy; R component was rated +/-5% and that would be the baseline for any wideband application, reference point at DC.

I could have gone nuts on the theoretical analysis, spending many nights in rigorous mathematical whatsis to satisfy some school instructor's "theoretical" demands on paper. I took a more practical engineering approach of DIRECT APPLICATION that would resolve the apparent two-port model equivalent. [I'd already learned that electrons, fields, and waves don't obey all human notions of how they work...:-)]

TIME is the most precious commodity we all share...at work as well as in hobbies. That applies to everyday practical engineering where it is quicker, cheaper, and more realistic to MEASURE some unknown rather than go through a school exercise of "analysis" taking hours and hours from First Principles on up...or argue excessively in some newsgroups on the whichness of the what. :-)

Based on some practical experience getting HF through microwave region range electronics to work, I'd have to agree with all those who pooh-pooh all the "deleterious effects of parasitic elements" of components. Those don't appear to be enough to worry about on film resistors on up into VHF. If there's a concern about it, then those concerned should MEASURE it if they can't find data to suit.

Dear Music Lovers,

I was going to buy my own commercial FM radio station and changed my mind. It feels like only rich people can buy radio stations anymore.

So I decided to start "Radio Free Colorado".

Radio Free Colorado's achievement is:

1. We play popular music you don't hear on the radio anymore since "Corporate America" (companies like Caelr lneahnc Mmconusniot) took over control of the radio broadcast industry and companies like nosoo took over control of the music recording/distribution industry. These corporations submit "playlists" to over 90% of the commercial radio stations in the U.S.

A playlist is just that: if a song isn't on the list, it doesn't get played.

2. To play carefully selected, current multi-genre popular music (no "Bratyen" or "Ashell" type artists - ever!) -- but we think Coldplay, Modest Mouse and Norah Jones are just fine.

Radio Free Colorado plays a lot of music you probably haven't heard in such a long time and have since forgotten how much you love. It's such a thrill when a forgotten song comes on and you say "Hey, I love this song" and all your fond memories of it come rushing back to you.

Radio Free Colorado is NOT beholden to anyone. There is no pre-approved "playlist", no one tells us what we can't play. Listeners can, however make song requests and if we have it we will play it.

Radio Free Colorado streams music LIVE over the Internet using a high-fidelity 128 kbps MP3 stream. We use professional and modified sound processing equipment to achieve a sound quality which we believe is superior to virtually all other 128 kbps streams.

Any computer with a DSL, Cable Modem (or faster) Internet connection that has a download speed capacity of at least 128 kbps can tune in.

No streams slower than 128 kbps are available.

Virtually all MP3 music players are capable of receiving live MP3 music streams over the Internet. Any music player compatible with streaming MP3 audio can receive Radio Free Colorado's broadcast.

Our MP3 broadcast stream is compatible with virtually all music software programs and works with PC's running Windows, Apple computers running OS X and other machines running Linux or Unix.

Our "Genre" (what kind of music we play) is VERY diverse. We play Modern/Classic Rock, Progressive Rock, Alternative (Modern and Retro), Pop, Billboard Classics, and Top Radio Hits from the 60's, 70's, 80's and 90's. We also play some Ambient/Instrumentals. No Rap or Hip-Hop, Classical, Jazz or Swing.

Radio Free Colorado is located at the website:

http://www.boomspeed.com/garyburke/radiofreecolorado/Radio_Free_Colorado.html

While you are listening to our stream, you will see the last 10 songs played along with complete information listing the Artist, Album Name and of course the Song Name.

To contact Radio Free Colorado during our broadcast for song suggestions, requests, questions, etc. you may:

1. Use our AIM address: radiofreeco
2. Use our e-mail: garyburke@boomspeed.com

Can we consider a standard car ignition coil a Tesla coil ? A cheap,
reliable and simple one.
There is primary with capacitor in distributor and secondary with self
resonance of course.
Good high voltage insulation is achieved with coil in oil bath .

Can we consider TV line transformer a Tesla coil or purely a transformer ?
It is produced to resonate in selected line frequency

I wonder how is normal neon light high tension generated.
Do they use some kind simple tesla coil system to ionize the rare cas inside
the glastubing or are they using choke like normal fluorescent tubes.
In any case neon lights seem to be safe for public with very simple
construction.
Safety protection with fluorescent lights is much and more complicated and
failsafe.

Avery, I too have had a similar career to yours. I cannot but agree with all that you say. A very apt description.

Regarding newsgroups - "Abandon all rank ye who enter here." (Toc-H, on the Western Front, 1916.)

To summarise -

To find what a resistor does , measure it.

If you are unable to measure it then model it with lumped components and then calculate.

If lumps are not accurate enough then model it as a distributed transmission line, which it actually is, and calculate again.

If you get similar answers for both procedures then you are laughing.

If you don't know how to do these things then you are not qualified to call yourself an engineer which I'll admit is slightly off-topic. But if the cap fits then wear it!

Regards, Reg.

>Good high voltage insulation is achieved with coil in oil bath .

A car ignition coil isn't tuned primary to secondary - Frequency is
much lower than all but the largest tesla coils. Most Tesla coils are
air-core transformers. Induction coils seldom put out the voltage of
tesla coils. A moderate TC can output 100,000 volts compared to
20,000 for a car ignition coil. 250,000 volts isn't hard to get out
of a TC.

>
>Can we consider TV line transformer a Tesla coil or purely a transformer ?
>It is produced to resonate in selected line frequency
>
Flyback transformers have some of the characteristics of TC's, but
usually much lower voltage, and their frequency is lower. I don't
believe they are resonant - but don't know for a fact. Secondary
isn't series resonant. A color CRT may go up to 50,000 volts.

>I wonder how is normal neon light high tension generated.

They used to use current limited (magnetic shunt) line frequency
transformers that relied on turns ratio to step up the voltage. Most
of them still do use this type of transformer. When the gas in the
tube ionizes the current limiting of the transformer protects the
transformer.

>Do they use some kind simple tesla coil system to ionize the rare cas inside
>the glastubing or are they using choke like normal fluorescent tubes.

The more modern neon sign systems do use high frequency/ high voltage
generators because they are cheaper, smaller, lighter, and safer.

>In any case neon lights seem to be safe for public with very simple
>construction.

Neon signs and neon sign transformers aren't all that safe. Many are
current limited below the ~100 ma necessary to kill (but 100 ma is
just a number; they didn't arrive at it empirically . . .) Look at
the controversy surrounding taser weapons - much lower average current
and power than a NST.

>Safety protection with fluorescent lights is much and more complicated and
>failsafe.

The ordinary magnetic ballast fluorescent lamps have the usual line
voltage hazards. I wouldn't consider them any safer than incandescent
lamps.

High frequency fluorescent lamps may be somewhat better - but the one
I just took apart does not have line voltage isolation. Looks like
they just rectify the AC line than chop it at a high frequency and use
a small choke to limit current.

Fail safe? How do you figure?

Thanks for reading this posting. I'm looking for hens teeth in the form of the mic gain pot for the 32S3 transmitter. It is a dual section pot with 500 K on one section and 2500 ohms on the other. The switch is closed when fully CCW, not open like most switches. I've already taken out a second mortgage in the event I can find one of these...

73s,

Evan

Are you talking about the QRPp magazine and the Homebrewer Magazine?

QRPp was the old Norcal quarterly and Homebrewer was the old NJ QRP Club Quarterly.

They merged with a few other clubs to form the AmQRP Club.

You can learn more about the AmQRP group from http://www.amqrp.org

Norcal has supposedly split away from the AmQRP and has their own website but I think AmQRP is still selling the NORCAL kits. I know Doug Hendricks left AmQRP last month I think. (http://www.norcalqrp.org)

I THINK originally, if you had a sub to QRPp and/or Homebrewer you were given the same number of issues to the new replacement quarterly the AmQRP Homebrewer but don't hold me to that.

I think George Heron N2APB is in charge of the magazine, but not 100% sure about that now.

AmQRP Homebrewer has sent out a total of three issues of their magazine since the club formed late in the summer of 2003. They currently have #4 ready to ship according to the website, but it was supposed to be in our hands in early November....about 3 months late...but we still don't have it. It's now missed two or maybe three promise dates already.

The website is still up, and they put out a message near the end of October or first part of November saying they were goin gto be making some big changes and things would be a lot better soon.

I think most QRPers are like me, and taking a "we'll wait and see what happens next" kind of stand.

The three issues of the AmQRP Homebrewer we got, were very good magazines. I don't know what the hold up is now.

Evidently, not completely spit away, but an associated club like the ScQRPions and NoGa. But no longer a partner like NJQRP. I can't say I really know what that means, but I think the main thing is that NorCal will be doing their own kits.

> I think George Heron N2APB is in charge of the magazine, but not 100% sure
> about that now.

yep

> I don't know what the hold up is now.

I'm guessing that they are basically out of gas. George seems to do about 99% of the work, and he seems to have a really heavy-duty day job. I could be reading the signs wrong but I get the impression that every now and then his employer gets on an acquisition binge and he ends up flying all over the planet. Sorta tough getting the mag out when you are sitting in an airport in Thailand.

A few months ago they had 5 or 6 kits that simultaneously got very popular. Assembling all those kits pretty well fried the volunteers. I think some of it is simply recovering from that, and learning to be a little more disciplined in retiring kits.

I get the distinct impression there is some politics getting in the way, too. But I can't say that for sure since I make it a point to avoid that sort of thing. This is one of those areas where ignorance really is bliss.

>voice announcements.

Seems that it is starting to play role in QSK and contesting. Latest TenTec Orion seems to be having problem with QSK above 40 wpm.

The other effect is some loss of inteligibility on weak signals. My friend OK2RZ who started to use TS870 immediately complained about the inteligibility as compared to straight analog RX. Audio sounded mushy to him, more difficult to copy weak signals in the noise. To me it was a surprise, but he is appliance operator with good ears and when he compared two types of rigs, he pointed out to mushiness of 870 (esp. weak) signals.

We are considering this in the design of Dream Radio One, where heavy computer, DSP and analog hybrid is coming to play.

Looks like DSP is here to stay, has some advantages, but will need some fine tuning (no problem, digital stuff, right?).

I notice they say "very low inductance" but it would be nice to have a
figure!!!

The "mushiness" sounds like the ADC or DSP data paths aren't deep
enough, so the weak signal is getting lost in quantization noise.
That's unfortunate, so make sure that your "dream radio" has plenty of
"footroom".

Well, Reg, equivalent circuit modelling is not a common topic taught in colleges, _especially_ in an undergraduate curriculum, and there are one heck of a lot of EE's out there who work for companies that don't even _have- the facilities (a network analyzer) to properly measure what their resistor does... yet plenty of them are fine engineers.

Electrical engineering is quite broad these days. There are guys who sit around designing communication systems who never touch soldering irons, and I'm sure plenty of them would claim you're not qualified to be an engineer because you can't derive some 'trivial' convolutional code off the top of your head.

BTW, many SPICE simulators do a mediocre job of simulating lossy transmission lines. Most people who are going to be using components at frequencies where they care about distributed parasitics are probably (hopefully) using frequency domain simulators anyway, but that too is an area where today's undergraduate curriculum tends to be somewhere beween weak and non-existant. (Using simulators other than SPICE... e.g., harmonic balancers, periodic steady staters, linear frequency sims, etc.)

I would guess your friend is complaining about the TS870 DSP when used in the phone modes. I don't use the phone modes, but have tried it there and would agree it seems to make little improvement. However I do use the TS870 exclusively on CW and can say that the DSP is extremely effective in that mode. To the ear it makes a 559 signal sound like a 599 signal, and a difficult in the mud weak signal reasonably copyable. The background noise is really reduced and cuts way down on operator fatigue. The bad part is that the CW note is messed up somewhat (but still easily copyable) and at speeds faster than around 35 WPM it can not keep up and runs the notes together ruining copy. But in my situation using a low stealth loop antenna in close proximity with computer, cable, AC lines ect, the TS870's DSP is a lifesaver.

I wonder, though, if the AADE meter is not getting confused by the
resistance of the resistor. The fact that the measured inductance is
just about proportional to the resistance might be evidence for that.

Duncan has kindly sent a couple of samples, with duplicates that have had the paint scraped off. I just arrived home from a few days away, so haven't had time to measure them yet.

Each one is only an open spiral of about two turns along the whole length of the 3W resistor body, so you can see immediately that there's no way the inductance can actually be more than a few hundred nH.

This actual, physical inductance is in *series* with the resistance. What seems to be happening is that the AADE meter displays the resistance and reactance in their equivalent parallel form, which is a function of the measurement frequency (which varies, but is understood to be in the order of a few MHz).

Guessing a frequency and then doing the parallel -> series transformation on 22 ohms in parallel with 4.5uH produces results in the right ballpark: R is still around 22 ohms but the *series* inductance is 100-200nH.

I will try to measure the resistors tomorrow.

Mike, I think you've hit the nail on the head. To be fair to AADE, they warn that the 'Q' of the inductor has to be reasonable to get a sensible measurement.

The kind of measurement frequencies we are talking about are in the order of 700kHz. At that frequency, the inductance of the 'indicated' 4.5uH is 19.8 ohms, not a million miles from the 22 ohms of the resistor itself - this is not what I would call a reasonable 'Q' value. Fair play to AADE, it's designed to measure the inductance of inductors, not other components ;-)

There is an additional complication in that there is another inductor in
the box itself of 680uH, LX (or should I say RX) is in series with that.
It's late now, but I will try and work out what's going on tomorrow night.

==========

These roller inductors can often be found at ham flea markets . Residing in Belgium you might have an opportunity to visit some of the many flea markets in the Netherlands . There is a really big one in March every year at Rosmalen near 's Hertogenbosch. Another one is the open air ham flea market at the 'Lichtmis' trucker's stop between Zwolle and Meppel (last Saturday of September).
I have seen roller inductors for sale at any ham flea market in NL ,also new ones .

Good Luck

==========
Before using drain pipe check it for RF integrity in the microwave oven. The
grey stuff seems to have metal containing pigment.
The white stuff might be better .....suggest you always check.

Another possibility might be a polystyrene cylinder in the shape of a liquid
volume measuring gauge as used by photographers in the dark room .
I have such a gauge made by JOBO - Germany , volume 500 milli-litre
,diameter 65 mm (approx 2.6 inch), length 200 mm (8 inch).

==========
Don't know the US situation ,but in Europe the marine 2 MHz band (in
particular 2182 kHz emergency channel) is no longer used, with most ships
now having satellite comms.
All that redundent equipment is now being dumped or made available via the
surplus trade . They all have variometers. However these variometers are
probably only usable up to 10 MHz.
Recently I was given a low power life boat emergency transceiver made by
SKANTI (Danemark) for operation on 2182 and 8863 ? khz ,fitted in a water
proof enclosure .....beautiful components including a variometer.
Skanti also made the wellknown Sailor marine radio (painted green).

> 2/3 of it is close wound, and one third is wide spaced.
==========
If you don't have a MFJ-259B antenna analyser (also capable of measuring
inductance at actual freq in range 1.8 -174 MHz)
,you might be able to borrow one from a local fellow ham.
It's an excellent instrument for such a purpose. It enables you to make a
graph at every turn at the desired frequencies
The wider spaced turns are probably used for 'tuning ' the higher
frequencies where the capacitance between the turns becomes a significant
factor.

==========
You are riding my hobby horse.
I find the obligatory 599 or 59 report absolute nonsense , if not stupid ,
especially in connection with contests ,because it does not provide 'any
information' . Instead one could be required (also on HF) to report the
IARU locator like for example IO87AT followed by a serial number.
However this would no doubt cause havoc among the 'mega-scorers' since it
would be much harder to copy instead of the fixed 599 or 59 , resulting
in a lower score. Although a computer database could link a callsign to
the IARU locator ,this would be more difficult, if not impossible,during a
field day or similar event.

==========
I have read somewhere that it was Art Collins , of Collins Radio fame ,who
first mooted/established the above standard for up to 30 MHz. Much later
,among radio amateurs, the S9 signal level for freqs above 30 MHz was set
at 5 microvolts into 50 Ohms .

There's a serious shortcoming with variometers for transmitting purposes.

As the inductance reduces the wire resistance remains constant.

Result - extremely low Q for small inductances.

Folks are starting to experiment with reflow soldering in toaster ovens. I've read good reports on the web, but have absolutely no personal experience nor have I even talked to someone who's done it, so I can't vouch for it. One of these days I'll give it a try, in the meantime you can search on toaster oven reflow and get a slew of pages.

There's at least one company (www.pcbexpress.com) who'll even make prototype stencils for your solder paste, although for stuff that's not too fine you can dispense paste from a syringe.

Get a decent temperature controlled soldering iron, run it at 600F/315C and use low melting point solder. No need for preheating or any other messing about.

On some boards chips can be tricky to remove because they are glued in place.

Steve

So, like you want me to sit at the rig with magnifying glass and observe the meter with 5% accuracy?
Reports became largely redundant, most people chose to 59 them, but nobody is stopping you from using accurate report. It just became more important in the contest to work as many as possible, fast, rather than do scientific reporting on signals. The other purpose is to alert the recipient that the other part of exchange is coming.
Most established contests are using signal reports (old requirement for DXCC QSOs). Some newer ones and VHF are not.
Check http://www.computeradio.us/TeslaCup.htm for really fair and modern HF contest rules.

73 and 599

That's whay (as an earlier poster in the thread mentioned) VHF contests
are more honest. The exchange has to be the (correct) grid square.

Thus, the contest judges have a excellent way to locate mis-matched
calls:grids.

> Fail safe? How do you figure?

Thanks for your comments to the various questions.

Maybe my English impression was poor.
With fail safe I was meaning the safe construction which is controlled by regulations and paragraphs.
In outdoor use and in moist places standard fluorescent tubes, their wiring, chokes and igniter are never allowed to have open construction. (at least here in Nordic countries)
Similar situation is not with neon lights on the walls. Sometimes there are bare without any enclosures.
I even remember having seen the end wires of the tubes visible.
Well - normally neon lights are rather high so that people cannot touch them.

Risto

If the reactance is much lower than the resistance, it's generally inconsequential in a practical application. I think that's almost always the case for carbon film resistors, and I suspect it's nearly always the case for metal film resistors.

Probably, if the Q is so low as to make measurement difficult, it's probably low enough that the X isn't important in a practical application.

The filter will be a single crystal with a phasing cap to adjust the null frequency. I need two signals 180 degrees out of phase which I will get by using two capacitors across secondary with the center grounded. This is the scheme I used years ago and never found another scheme that worked as well for me.

>AS time and the Q rate is important and everyone is going 599, why don't
>the contest rules just do away with that requirement ? What good is it ?
>

Does not take all that much time with 5NN and it is kind of allert what is coming. In CQ WW where report and zone is exchanged, even that is redundant, unless one is in weird zone, then you have to watch the real response. Report inclusion in contest exchange is from the old QSO/QSL requirement for awards to be at least 337. With all the super duper equipment and perfect propagation everybody is 59/599 :-) So if you hear the station, it's 59, if you don't hear it well, need few repeats, he is 59 after all :-)

With some operators going at 460 QSOs/hour, something has to give. Five Nine also becomes FyNy. Saves few lips.

If you want to "punish" me and throw 47 at me in the contest, I would appreciate any point I can get and I would duly record that with extra two keystrokes.

As far as S-meters, it should be illegal to be stronger than S9, it complicates the things. Over S9, very 6 dB we should use alphabet A, B, C .... to stay with single digit.

Funny one happened once with huge pile-up on a rare DX. Calling was never ending, when finally died, because DX wasn't coming back to anybody, he came back with "All of you, you are 59, XX5ZZ" You should have heard the dead silence on frequency :-)

> (adds) ..... at the test frequency

Sure. Any statement about a frequency-dependent property like X or Q applies only at the frequency at which the component has that particular X or Q.

As you raise the frequency, the X of course increases while the R stays relatively constant. But other effects like shunt C and the physical length of the part eventually start coming into play, making the simplistic model of a series RL inadequate. My general experience has been that I can ignore the inductance of leaded carbon film resistors up to a frequency where the leads and component length become a problem, and I need to go to chip components. I've never seen significant reactance from the trim cuts on a thick film chip resistor -- the shunt C across the narrow cuts pretty much makes them invisible.(*) I suspect that carbon film resistors likewise have a narrow cut. But I don't have much experience with metal film resistors. I assume the base material has less resistivity, so is probably cut into thinner strips with more "turns" and more spacing between "turns". So there might be a combination of R and frequency where the reactance is objectionable, below the frequency where you need to abandon leaded parts. I'm watching this thread with interest for any good measurement results. I could try

making some measurements up to 1.3 GHz with my 8505A network analyzer, but I wouldn't trust the results. I think the measurements probably would have to be done on a system with good, computer-directed calibration, a good set of calibration standards, a decent and well-characterized test fixture, and an operator who's very familiar with the many traps you can fall into when making subtle measurements like these -- and I have none of the above.

(*) I've used thick film resistors at frequencies up to 20 GHz or so, in very sensitive time-domain applications. In those applications, I modeled nearly every component as a transmission line or a pi or tee approximation to a line, with the R in one or two lumps. Those models agreed quite well with actual results.

OK, so this is basically emulating the reflow process. The only issue with this is that there is no real temperature control and you can damage both the board and the components if you are not careful (as is the case with all soldering).

The technique I use is lots of flux and a soldering iron. It is key to use flux so that the solder flows properly. Sometimes a microscope is required and then occasional washing to remove the solidified gunky flux [wash in ethyl alcohol]. However if you want to solder an IC you can run the soldering iron along the side of the IC. Slope the board and then run the soldering iron down the board from the top most pin to the bottom most one and the solder meniscus will stick/flow with the soldering iron. You will end up with the last 2 or 3 pins with a bridge which can easily be removed with solder braid. You do however need to tack the IC down to start off with so that it doesn't move whilst soldering. I learned this from a very skilled tech and it works incredibly well. Especially for 25-50mil pitch QFPs. For Passives, it's a lot of work and the technique given in the link below may be better if you have lots of them.

FLUX is always key though! Water soluble if possible as it's easier to clean off. Just wash it and wait for it to dry. Don't try and heat it dry since this can cause steam to form under the solder joints (and the ICs) and cause adverse pressure. The pressure can cause joints to fail and parts to crack.

I would also like to point out something else about the technique given in the link below. Bake out! One real issue in SMT soldering is that IC's have to be baked out if they've been sitting in a normal environmnet (humidity) since the epoxy absorbs water. The water then gets heated by the IR reflow process/oven and can cause the IC to crack. The way around this is to heat the IC/components gently to above 100 deg C (125 deg C is OK). This bkes out the water. USually in an industrial process this is done for about an hour or 2. The IC's are then sealed in a waffle tray and bag with anhydrous silicone crystals to make sure no water gets reabsorbed. You shoudl only be wary of this if your IC's have been lying around in a damp warm atmosphere for a few days. For normal prototyping this is not so much of a problem.

You can also get the reflow "hairdryer" kinds of devices. These work well also and are a little bit more controllable than an oven. If you paste as described by the link below, just heat around the IC/components until the solder goes shiny. It'll reflow at that point. Let it cool off and check it.

Interesting. I'd probably call what you refer to as "fail safe" as
"foolproof."

Do you have stricter regulations regarding fluorescent lamps versus
other line operated electrical appliances?

Perhaps the reason for stricter controls is the fact that fluorescent
lamps are frequently used in family residences.

Or, perhaps they are concerned about electromagnetic fields - here it
is politically unpopular to even hint that low frequency emf's can be
damaging to health. I've read that some Scandinavian countries are
considering imposing LF EMF limits or are already doing so. Do you
know anything about that?

I see the same things with neon tubes here, particularly in the older
establishments. Wires with just a plastic or glass sleeve over the
connection to the tubes and not protected from water or hands.

The transformers usually have a secondary center tap that is grounded,
so each side of the neon tube only sees half the total high voltage.
But half is still a lot . . . My smaller transformer is 10 KV @ 30 ma
(for ignition on an oil furnace - but identical in construction to a

NST). I can't imagine it feels good if one were to get body parts across it. It is designed to start fires . . . I'm not about to try it and I don't know anyone who got shocked by one.

One correction to my earlier post: The common style of car ignition transformer relies on a rapidly collapsing magnetic field to produce a spike of high voltage, not just the turns ratio. Field builds slowly and collapses fast.

If the same induction coil were used with a capacitive discharge ignition circuit, the turns ratio and high primary voltage produces the high voltage.

Can't help with knobs.

An idea for a scale: use a computer, printer and drawing program to
create a scale. Print on paper and sandwich it between the chassis
and a clear plastic cover.

I only added that because the test frequency was cited as ~700kHz and a casual reader may have taken the above to mean that the X was insignificant at the frequency of intended operation.

I am lucky this morning. I have received two identical roller coils from France (35 µH each), scrapped in the 70's (and sleeping for many years) from an old French submarine transmitter. And in a very good mechanical and electrical state. Now I will buy some stepper motors for positionning.

I also have received a few days ago by e-mail from Bob (anonymous) an interesting article taken from QEX about the building of a roller coil and some good ideas about stepper motors. Thank you to all.

Ah, thanks, I'd missed that. At 700 kHz, you'd never get enough
reactance from a metal film resistor to be bothersome, and I doubt that
you'd even be able to measure it.

Over a range from 50kHz to 50MHz, Duncan's two resistors measure about
22 ohms + 31nH, and 33 ohms + 23nH.

To avoid having to construct a special test jig, I measured each
resistor with about 30mm of bent wire leads, which would account for
about 20nH of those measured inductance values.

The very low inductance of the resistor body is completely consistent
with the physical construction. On closer inspection, the metal film is
an almost continuous tube, with a very narrow spiral gap of about 1.5
turns. The gap adjusts the resistance by slightly increasing the overall
electrical path length, but it adds very little inductance.

If you used very short leads instead of the longer lengths I had to use,
these resistors would have a low SWR up to at least 144MHz.

Thanks again to Duncan for supplying the resistors.

Ian, if it's not too much trouble, I'd be very interested in how the measured inductance compares to that of the resistor body/leads only. I'd think that could be done by coating a similar-size resistor with conductive paint or foil and measuring with the same method. The difference between this measurement and the one you made would then show how much inductance is due to the spiral element, and would represent the minimum possible inductance for that resistor body type and lead length.

I could certainly do that, because Duncan has supplied pairs of
resistors: one in original condition, and the other with the coating
cleaned off, just ready for painting.

However, the difference in inductance is going to be very small, and I'd
need to build a test jig that can keep other stray inductances under
control.

Over the weekend, maybe...

If the US had not become involved in WWII you Brits would be speaking
German today. There was no way England would have defeated Hitler
without the US help.

psst, it was Soviets who did more to defeat Germany than all the other
Powers combined. With a fair amount of material aid from the U.S., yes, but
it was their blood. And, no, I am not belittling the sacrifices made by U.S.
troops. My father fought in Africa, Sicily, Italy, France, and Germany and I
have his Sliver Star, Bronze Star, Purple Heart, etc. as a proud reminder.

It is interesting to note that if you look at one of the winners (Robert Lacoste) of the Circuit Cellar design contest (Steve Ciarcia's embedded microcontroller design magazine) ... he addressed many of the issues that you raised.
http://www.circuitcellar.com/library/print/0704/Lacoste_168/index.htm

In fact enough, with a $150 toaster oven and a low-cost controller, he achieved reflows with good results. A few mfg. were very interested in his design and approach (Robert has his own consulting company in France).

The idea was to measure the coated resistor under exactly the same conditions as the regular one, so couldn't you just use exactly the same setup as before?

Afraid not... In the present setup, the main contribution to the total inductance comes from the long, floppy resistor wires, and I couldn't guarantee not to disturb their configuration while applying conductive paint to the resistor.

To get a reliable answer, I'd need to reduce the lead length and make the whole thing mechanically more stable.

Actually it was the Japanese that caused Hitlers defeat. Think about it.
If Japan would not have attacked the USA, Hitler would not have had to
declare war on the USA. Which would have given him a year or two more to
work on the USSR. And maybe, just maybe, hold onto Africa and thus giving
him a serious shot at winning it.

But...the USA came in and gave him another front to contend with. Basically
the Allies got lucky.

From: ab <abracadabra@hotmail.com>
Message-ID: <_Fjsd.1050$EI1.660@reader1.news.jippii.net>
Source record: 21751

hi!
I made a few mods to my Good Ol' Icom 735 and it's now called Icom 735 PRO, still going strong since late 1980. A few I found on the internet, but the filter mods I have not seen anywhere.

Here is a list of what I have done!

- unlock mod: transmit outside the amateur bands.
- change squelshpot for the rfgain slide: very convenient in use
- change rf attenuator from -20dB --> -10dB: -20dB is really too much
- check and modify PLL time constant: if you have a late model, the mod is needed. It results in less spurious signals.
- check the solderings for antenna and rx connector.
- replace the lower IF (455kHz) SSB-filter and add a new 455kHz narrow CW-filter, 500Hz or 250Hz.

This last mod needs some skills in electronics, but makes wonders to the receiver compared to the barndoor-wide original filters. I use the big 455kHz x-tal filters from Yeasu FT-1000. 2kHz SSB filter and 500Hz CW filter. They just fit in between the main board and the front panel. If you don't like the narrow 2kHz on SSB, you can use the 2.4kHz wide if you can find one. 2kHz is recommended for contest use in a any case...

I'd love to hear if you can add something to this list!

cheers,
cb

ps
I love these old more or less analog radios where it's still poosible to make repairs at home and mods and don't have to look for firmware upgrades. A radio is a radio, not a computer :) (just changing the PA transistors on my Very Old (1978) TR-7 to get it running again)

pps
I also rebuilt my Old (mid eighties) Dentron GLA-1000B. Not much left of the original construction. Added 160m, changed the very expensive original tubes etc etc...400W

key down output on all bands from 160m to 10m including
WARC bands. Nice small package and cheap compared to
vfets, hi!

3968. FT-902 intermittent RX problem

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-12-04 17:42:37 UTC
From: J M Noeding <la8ak@online.no>
Message-ID: <ict3r051vrlcbc31agtso0kud5rtlgbdb0@4ax.com>
Source record: 21752

It seems to be a problem with intermittent contact in antenna relay or attenuator, so I wonder if somebody has some experience with softening voltage for switches and relays?
The relay and attenuator for FT-901/902 is shown on
http://home.online.no/~la8ak/93a.htm
(perhaps somewhat bad quality when you don't know already what it is?)
A simplified circuit diagram is shown. Decoupling capacitors are not shown. Wonder what sort of softening current is needed for some improvement? Suppose 13.5V is a practical limit to avoid too much current transient.

3970. Re: Tesla Coils

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-12-04 19:09:59 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <cot227fga1@titan.btinternet.com>
Source record: 21754

The essential difference between a Tesla coil and all the others, such as ignition coils, is that the Tesla coil is designed to makes full use of a high coil Q.

Coil Q = Coil Reactance / resistance.

i.e., it makes use of the resonant rise in volts across a tuned circuit with high inductance, low (self) capacitance and low resistance.

It has to be physically large to obtain a low wire resistance combined with a high inductance of many turns. In addition, of course, the large physical size enables very high voltages without flash-over.

Optimum resonant frequencies (very non-critical) for home constructors are between 50 and 150 KHz. The lower the frequency the higher the voltage. Use a ball or a thick ring on the top to minimise corona discharge.

It's as simple as that. I hope this description will enable you to make your own Tesla coils. But in this day and age they are mainly of educational and entertainment value. Perhaps they always were. Tesla was a flashing-light with bangs, circus showman without knowing exactly what he was doing.

Ingenious nevertheless. But perhaps not quite in the same class as Edison. Even Edison and people like Marconi did not know exactly what they were about.

But we should be very grateful to the few workers, the willing slaves of technology, between 1880 and 1905 who dragged the human race, often at great personal disadvantage and expense to themselves, away from the feudal age into the present age of electronics.

The $64,000 question : what is the human race, you stupid set of succeeding genocidal suckers, to do with your rich inheritance?

Too late to ask Tesla.

Tesla was a genius cruising through life, having fun, without caring
or worrying about the ramifications of his toys.

>Ingenious nevertheless. But perhaps not quite in the same class as Edison.
>Even Edison and people like Marconi did not know exactly what they were
>about.

Not in Edison's class. A class an order of magnitude above Edison
perhaps. Edison and Marconi were more interested in profiting from
their inventions (or their refinements of the inventions of others).
They can be honored for their commercialization of inventions and
bringing the ideas out of the laboratory. Thomas Edison had a lot in
common with Bill Gates in that respect. Tesla probably understood his
inventions better - to his way of thinking the induction motor and
three phase power were so obvious they didn't warrant much discussion
or interest.

Many of us fall into ruts and become worker bees. From birth we are
programmed to seek safe secure ruts . . . Some of us just cruise
through life. The "successful" apply the efforts of others. Little
is done with the "betterment of mankind" as its real justification.

Humans just continue to react/respond to the conditioning of millions
of years of evolution. We can see that something better should or
could be done with what we have. But we don't.

All of our flaws and gifts are what enabled us to survive. We still
play those cards - even though we changed the game substantially in
the last 4,000 years.

>
>Too late to ask Tesla.

Now that would be interesting.

>Reg, G4FGQ
>

Playing with Tesla coils has been very educational and has altered my perspective a great deal. For instance, I groked the concept of SWR with a detached cerebral understanding until I saw it in a Tesla coil. Ditto harmonics. I understood that inductance is related to the square of the turns, but it was so much book learning until I built an induction coil.

Likewise I thought the 1600's to 1900's were the dark ages scientifically - then I read some of the old masters and realized that they were very smart cookies. They had to deal with concepts that they didn't have the language to describe, yet they still understood what was happening. They frequently resorted to mechanical models in an attempt to make it physical and understandable. Imagine what they could do with the oscilloscope I take for granted.

I rank Hertz, Gilbert, Maxwell, Kelvin and Tesla among the gods, and Edison and Marconi among the mortals.

And . . . if you go back just a few more millennia, the inventors of musical instruments were dealing with the same concepts that Tesla and Marconi were playing with. Likewise the first engineers trying to manage crop irrigation or heat a bath. Doubtless they were equally brilliant; they just didn't have the base to build on.

Beer, particularly home brewed beer, is very high in vitamins
naturally. When one buys a "B" complex tablet, one is buying the
dregs of a brewer's fermentation vessel.

It is not required (or allowed in the US) to label the nutrient value
of beer. People might actually start drinking it for health reasons.
Yikes!

Off topic for sure. There does seem to be a positive correlation
between engineering and beer brewing. One for alt.beer.home-brewing
or alt.homebrewing

From http://www.restaurantreport.com/departments/b_health.html

And if anyone is curious about the specific vitamin content of
beer, they need look no further than the legendary nutritional
information panel that appeared briefly on the six pack
carriers of Grant's Scottish Ale from Yakima, Washington.

Legendary? That's right, when the brewery made their the
nutritional information public back in the early 90s, (after all,
even bottled waters are required to display it), they got a call
from the Feds asking them to cease or desist, or something
like that. To this day, no beer carries any nutritional
information on its packaging.

3977. Re: Metal film resistors?

I use them with no issues that I know of.

Perhaps someone else has the mathematical and physical explanation.

I measured a few with my LC meter in the L mode and was unable to measure
any L.

Just a simple explanation. Not a comprehensive review. I do not know what
meter, nor the circuit.

Your depending on the circuit in your meter.
Some Inductance measurement circuits need the resistive component to be
canceled out (balanced by a bridge) to read the inductance. It doesn't mean it
has no inductance, only that he resistance values is much higher than the
reactance of the inductor. Therefore the meter sees the resistance only.

To make it even worse, not all MF resistors are inductive.

3979. Re: Looking for roller inductors

Thank you KN6WH,

I thought to this solution before but there are some problems: 1. My wyfe wouldn't accept a kind of double "laundry cord" in the house (plus all the hardware) - 2. walls are full of metal pipings (central heating, water, electric outlets, etc) - 3. passing properly through stone walls (sometimes more than 2 feet thick) is not that easy. This means that an indoor ribbon is automatically not acceptable. So the only solution is to convert balanced to unbalanced line. Outdoor I will use a balanced ladder line (home made) and a remote tuner (home made too) and indoor coaxials would be accepted provides they are installed in the corners and painted in white. This is why my original question was about how to find roller coils.
Somebody here gave me some addresses but warned me about the price. It was true: I was asked 500 euros for two new items. Hoppefully I have found two identical 35 ΅H roller coils (second hand) in France for 30 euros each.

If you sell it publicly, you have to get it FDA approved as it is now a
"food", and label it IAW them.
That is why the industry has not put in B vitamins into alcoholic drinks,
unfortunately.

This is the wrong newsgroup for you.

==========
Don't know type of relay in FT-902 .
If contacts can be accessed by removing cover ,try to slide a piece of paper drenched in contact cleaner a few times in between contacts .
I remember that this method was successful when I had a FT- 400 (a valve transceiver from the late 60s) ,my first transceiver which I used between 1985 and 1991 .

Sorry, wrong group!

rec.crafts.brewing group is what i intended to post in, although I got answers here! Thanks!

Making your own beer is remarkably easy and yes it is better for you. Better tasting too, and cheaper. I also am a shortwave geek (SWLer). Drop by for a listen and a pint.

the only possible way is to measure the VFO and consider that the BFO
freq for LSB and USB makes some difference, possibly 1.8kHz

> My freq counter have option (substraction and adding to IF frequency).
> Manual and schematics are at address below:
==========
Janusz, I have the manual for the FT-200 with the circuit diagramme.
The frequency counter input should be connected with a less than 10 pf
capacitor to the common switch contact of switch deck 'S1f ' being the
output
of V3(6CB6) , the premixer.
This output is representative for the operating frequency.
However the frequency counter offset is NOT the same for each band
I don't know whether your FT-200 has all the sub-bands implemented ,but I
shall list them all :

80 m 3.5 - 4.0 MHz premix freq range 5.0 - 5.5 MHz hence
freq counter offset : minus 1.5 MHz
40 m 7.0 - 7.5 MHz premix freq range 16.0 - 16.5 MHz hence
freq counter offset : minus 9.0 MHz
20 m 14.0 - 14.5 MHz premix freq range 5.0 - 5.5 MHz hence
freq counter offset : plus 9.0 MHz
15 m 21.0 - 21.5 MHz premix freq range 30.0- 30.5 MHz hence
freq counter offset : minus 9.0 MHz
10 m 28.0 - 28.5 MHz premix freq range 37.0- 37.5 MHz hence
freq counter offset : minus 9.0 MHz
28.5 -29.0 MHz premix freq range 37.5- 38.0 MHz
hence freq counter offset : minus 9.0 MHz
29.0 -29.5 MHz premix freq range 38.0- 38.5 MHz
hence freq counter offset : minus 9.0 MHz
29.5 -30.0 MHz premix freq range 38.5- 39.0 MHz
hence freq counter offset : minus 9.0 MHz

So you need 3 different offsets namely minus 1.5 MHz for 80 m band , plus
9.0 MHz for the 20 m band
and for all the other bands the offset is minus 9.0 MHz.
Suggest you use the smallest coupling capacitor necessary to excite the
frequency
counter and ensure the outgoing lead is properly screened and insulated ie
thin coax
(screen earthed on 1 side only to prevent an earth loop)
As a small 'capacitor' you can possibly use a short piece of (thin) coax.

Good luck

Frank GM0CSZ / KN6WH

1 Heathkit SB200 Amplifier (220v)
1 Ham M Rotator (cked by Norm)
1 Tail-twister Rotator (cked by Norm)
1 Cushcraft R7000 Vertical (40-6)
1 Cushcraft 80m kit for R7000 (never assembled)
1 LJE GP1, RADIAL PLATE FOR 2" MAST, 24 RADIALS
1 Minkota, mdl: 765 MX, 12v remote trolling Motor
(needs new prop)
1 18" Golden Rule for tournament fishing
1pr Replacement 8" Steel Wheels w/rubber tires
3ea ADULT MDL: KA1, KAPOK BUOYANT VEST,
(never in water), LIFE JACKETS.
1 Micronta FS/SWR Meter
1 B&W Dipole Connector [V shape]
1 Bag of various (approximately 10) Xtals, FT243
variety, HAM band frequencies.
1 3/8x24, Spring mount with 2 springs,
11ea Aluminum panels of sorts, 6"x12"x1/8"
3ea Packages of NICE-DUCT, brown color,
3/8"Hx5/8"Wx60"L, each package has 5 pc
totaling 25 feet.
1 12v WHINCH
2ea 50FT ROLLS OF RG6, 75 OHM COAX WITH "F"
CONNECTORS
1 25FT ROLL OF RG6, 75 OHM WITH CONNECTORS
1 CUSHCRAFT BASE RING FOR 10M RINGO
1 SHAKESPEAR FIBERGLASS, 144-174Mhz ANT,
SINGLE HOLE MOUNT
1 QUADSTAR 2M HALO
1 Motorola, MITREK, MDL: T81JJA4900BK, WITH
CONTROL & POWER CABLE - NO CONTROL BOX,
NO MIC OR BOOK (AS IS NOT TESTED)
1 Radio Shack, 8", Antenna Mast Wall Mounting BKT
1 Motorola, MICOR, mdl: 02033a, WITH BOTH CONTROL
CABLE & CONTROL HEAD AND POWER CORD (NO
MIC OR BOOK) (AS IS NOT TESTED)

1 AMPEX 8" REEL TO REEL TAPE RECORDER
1 INTERMATIC TIME CLOCK, 110v
1 SCHUMACHER 10/30/50, BATTERY CHARGER, 12v
1 CROUSE-HINDS 3 LAMP, (RED/YELLOW/GREEN), TRAFFIC
SIGNAL - ANTIQUE - WORKS GREAT!
1 AIPHONE AH108, 10W, 8 OHM, HORN SPKR.
43ea INNOVATIVE SIMPLICITY, MDL: CREST, 2-JACK WALL
PLATES WITH THE JACKS FOR TELCO
2ea SMALL PEDESTAL CAMERA MOUNTS
8ea GARDEN HOSE WALL BRACKETS
1 MOTOROLA, HANDIE-TALKIE POCKET RECEIVER,
MDL: HO3ANC-1000A, FREQ: 152MHZ, NEEDS NEW
BATTERIES, (NO MANUALS) (ANTIQUE)
1 MOTOROLA, HT TRANSMITTER, MDL: Z23NAC-1000A,
WITH MOTOROLA LEATHER CASE & MICROPHONE
AND COLLASPABLE ANTENNTA, NEEDS NEW
BATTERIES,(NO MANUALS) (ANTIQUE)
1 MOTOROLA, HT220, BRICK, 6 CH, W/MOTOROLA
SPEAKER-MIC, ON HAM BANDS, NEEDS NEW
BATTERY.(NO MANUALS)
1 MOTOROLA DESK CHARGER FOR HT220
(NO MANUALS)

If you are interested in any of these items, please send me an email with your offer. If I think it is reasonable, we will do business. If not then I will tell you.

I am in Montgomery County, Maryland, and would perfer not to have to ship, but if I do - please figure postage from 20895.

For the home-brewer:

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=5736402207

Still in factory wrapper.

Made of rigid 3/32" aluminum, the dimensions are roughly 7" wide x 6"
deep (front-to-back). The height is about 3" in back, sloping to about 1
3/4" in front. Two-piece construction, the side-bottom-side piece is
medium blue wrinkle, the back-top-front piece is a smooth off-white.
Bottom feet and attaching hardware are included.

Vy 73 es best DX,
theponyengine

One that minimizes unwanted or uncontrolled lead lengths. In general, one that is based on solid lumps of metal and large, broad, low-inductance conducting surfaces.

I had simply bent the resistor wires so that one end pushed into the centre of the VNA's N socket, and the other wire was literally tied onto the body of the socket. However, the measurement showed that most of the small inductance could be accounted for by those two wires - which you'd never leave as long as that in a practical layout.

To home in on the inductance of the resistor body itself, I'd have to build a jig that allows the wire lengths to be reduced almost to zero. Harold W4ZCB sent a picture of something he uses, which is just a brass plate soldered to the back of an SMA connector. The Device Under Test is then soldered directly between the centre pin and somewhere on the plate.

But I'm afraid my only visit to the workshop last weekend was to dump yet another cardboard box on the floor.

From: paul405 <nospam@ntlworld.com>
Message-ID: <ergtd.562$HQ3.361@newsfe3-win.ntli.net>
Source record: 21780

hi there
I wonder if anyone can help me .
I used to use a FARNELL L30 .05Ma power supply
for charging my NiCad's, very useful due to its current limiting
control however its quite old and unfornutally I have a problem with it
R27 has burnt out and I don't know what value it was
As its burnt and broken. and thus stopped working

and the large 1-ohm resistor dropped off with the heat
when the supply was accidentally short circuited
(Not by me, I but a friend. bugger)
I think it solders to the collector and emitter of the
oc36 can anyone confirm this ?

does anyone have a circuit diagram or a service manual
or can simply inform me what the value of resistor R27 is?

hope to hear from you soon
thanks

How about cutting the resistor's leads off completely and just
clamping it between say two 1" cube copper blocks? But then I guess
you would still have the problem of connecting it to the VNA. :-(

Have you tried Farnell ?
http://uk.farnell.com/jsp/home/homepage.jsp;jsessionid=1LUZNKK1DSU23QFIAEXCFE4AVAAS2IV3

Farnell InOne is a world-leading marketer and distributor of electronic and
maintenance, repair and operations (MRO) products. We offer our customers a
multi-channel choice for over 250,000 stocked products, providing a
comprehensive range of value-added services and tailored solutions to
support your business needs.

Farnell InOne is part of the Premier Farnell Group and belongs to the InOne
family of businesses. Including Newark InOne, the American based
market-leading electronics distributor and BuckHickman InOne, the UK's
leading distributor of industrial tools and supplies, the InOne family of
businesses work together across geographic and business boundaries.

Would possibly work OK if your standards were fabricated in the same way.
When it makes a measureable difference whether you're measuring to the front
face of the SMA center pin and the back of that same pin, you can start to
develop an appreciation for the accuracy possible with the VNA. I haven't
measured the capacity between two copper faces one inch square and separated
by the length of a quarter watt resistor, but it would be appreciable. (and
measureable if I were really interested.)

Please plan to attend Winterfest 2005, northern Colorado's
best winter hamfest and electronics swapmeet.

Saturday, January 15, 2005.
Doors open to the public at 8:00 am.

Admission of $5.00
Vendor tables available.
Door prizes (one door prize ticket included with admission)

Location:
McMillian Building at the old fairgrounds.
700 S. Railroad Ave
Loveland, Colorado

Contact me for information

That is more trouble to set up than is needed.

In order to measure any inductance component, the only
requirement is to find the DIFFERENTIAL between a direct
short across the bridge/RLC-meter connections and the
device itself (in this case a resistor).

Neil Hecht's excellent little LC Meter II does this automatically
by the zeroing button that subtracts the shorting inductance
from the device measurement, done arithmetically in the internal
microcontroller's registers.

The inductance of a standard gauge round wire is fairly well
known and has been around for years in texts. One can compute
that inductance fairly accurately without using a bridge/meter and
then compare that to the leads of the device under test. The
difference between the shorting lead and the device leads would
then be the inductance of the device-under-test's body.

If a few nanoHenries are involved and affect the circuit the device
is to be used in, the frequency would be high enough that skin
effect would be operative. Skin effect is the curious phenomenon
where current flows in thinner and thinner volume spaces near the
surface of a conductor. The thickness of the bridge/meter
connections would only be advantageous at DC (no skin effect at
all, only "straight" volumetric conductor bulk resistance) or lower
frequencies (where the "skin" is quite deep in the conductor). An
approximation of the RF resistance in Ohms/Inch-length is:

R_rf = (2.61 x 10^-7 x Sqrt(frequency in Hz)) / (2 x (w + h))

for PCB foil and where w = trace width in inches, h = thickness of the PCB foil in inches (about 0.002 times "ounce" rating of foil thickness, give or take some).

Reference: Nicholas Gray, Staff Applications Engineer, National Semiconductor, "Design Idea" insert in electronics trades for December, 2004. See also http://edge.national.com

However, when push comes to shove on measuring things, a built-in inductance might be as much as 10 nanoHenries. At 100 MHz that inductance is equal to +j 6.283 Ohms. A precision resistor of 50 Ohms at DC would have an equivalent series magnitude of 50.39 Ohms, an increase over DC of only 0.79%. The end result to a circuit using that device wouldn't amount to very much change.

If that inductance were (somehow) ten times higher to 100 nHy, then it would have +j 62.83 Ohms and the series magnitude would (of that 50 Ohm resistor at DC) be 80.30 Ohms. That WILL have some noticeable effect on a circuit at 100 MHz.

The upshot of all this is that one considers the frequency(s) of operation first, then measures a part second to find out if the resulting part inductance will have any effect on things. In order to measure the part, the characteristics of the measuring instrument ought to be known so as to get a reasonably accurate measurement. Comparing the part to a wide conductor across the instrument connections as the reference inductance, the part is then measured with the wide conductor inductance subtracted from the mesaured series inductance.

Some LC bridges measure admittance rather than impedance. If that's the case, then the complex admittance (an equivalent R & C in parallel) must be inverted to find the complex impedance which is a series R and L. A grid-dipper sort of measurement just won't yield any meaningful result for either Z or Y.

I need an aligator 2 meter amplifier for FM ragchews with people I've known for a long time but are now at a fringe ground-wave distance since I moved away from them. I'm talking about 300 (min) to 500 w output, and something like a pair of 4CX250bs in PP. The older ARRL handbooks have a pair of 4-125 in PP power amp which would be OK and I'd consider building one if its not a bear to tune, adjust, or neutralize. I also hear there are some affordable Russian metal ceramic tubes out there (one of the recent ham magazines) and I'd love to hear from anyone who can tell me if buiding around any of them is feasible and practical. Lastly, I think its Command Technologies or something like that that has a high power amp for 2 meters (using metal ceramic tubes) but I can't afford or justify their prices. Do the big brick amps hold up? My 80 w out LUNAR amp still works but my RFConcepts 160 out amp melted down. Several times.

The conventional answer to the above problem is to recommend more elements in the antenna and/or higher placement of those elements. For additional reasons beyond the scope of this post, neither of these options is, at this time, practical for me.

I'd appreciate hearing from anyone who has an old 2m aligator amp (working and stable) they would like to convert to cash. Or, if they have any other bright ideas (we're not going to get into satellites or Echo Link stuff, either).

I may not check my email inbox right away, so don't expect quick answers. Also, we don't take telephone calls when they ring and would prefer just sending an email to the address I am sending from.

73,

Art, W4PON
I'm in southern Delaware.

I do not have any such thing, but Fair Radio currently has a bunch of high power VHF aircraft sets. Some of them are just linear amps (and they have to be linear since this is AM) and some are full transmitters with plate modulation. Either one of them could probably be hacked up into 2M amp duty. The finals need to be retuned. I don't know what extent you'd have to add extra trap stuff if you were to move the bias point down, but hell, you can run FM through the class AB amp and throw away some power.

The aircraft VHF stuff is basically a glut on the market right now because there are a lot of upgrades going on, and the old gear is all AM and not very useful for ham service without some hackery.

Good point Bill, but remember that the Russians were using alot of U.S. goods in their efforts to defeat Nazi Germany. If it werent for the U.S. Merchant Marine they would not have had the initial supplies to keep up the fight.

I believe it was a total team effort on all parts. No one nation should take ownership of the overall defeat of a tyrant or a tyranical government of the time. Each had their own reason for entering and fighting and that is what should be respected.

I probably shouldnt bring this up but remember that the soviets did sign a
non-aggression act/treaty with nazi germany. They were only brought into
the war based on Hitlers ignorance in attacking them. Had he not broken
the treaty I would find it hard to believe that they would have entered
and sacrificed so many and and so much for the "western" powers. Remember
nazi germany just about took stalingrad.

They didn't "sacrifice ....for the western powers." We didn't sacrifice for them. Heck, we were not even formal allies (the official term was "associated Powers"). I never mentioned motivation. There seems to a common bad habit of associating "goodness" on one hand and "bravery" and "sacrifice" on the other.

It's not at all my intent to make up more work for you to do. What I was mostly interested in was just how much the spiral construction of the resistor adds to its inductance -- is it or isn't it significant, or is the inductance mostly due to the component size and the leads? And it still seems to me that you could just measure a wrapped or painted resistor in the same fixture as you did the intact resistor. The difference in measured inductances should be the contribution of the spiral element.

Although it would be interesting to see how small the inductance of a leaded resistor could possibly be, it's probably of more practical use to know the inductance of a leaded resistor with some realistic length of leads attached, which is I believe what you've already done. Anyone needing less inductance than that would be wise to abandon leaded resistors and go to SMD.

I completely agree that all impedance measuring devices should be "zeroed" in this way. But the problem with the resistor wires that we're discussing here is *additional* to that.

We want to know the inductance of the metal-film resistor body, with the wires cut very short as they would be for any application where low inductance is important. However, for convenience, my first measurements used almost the full length of the resistor wires to connect to the N socket of the VNA.

It turned out that the total measured inductance is comparable to what you'd find from the wires alone, so the body inductance is very small (which is entirely consistent with the physical construction).

The suggestion had been to determine the inductance of the resistor body by first repeating that original measurement, then applying conductive paint to short out the resistor body, and then measuring again. The body inductance would then be the difference between those two measurements.

Unfortunately that would be a poorly designed experiment, because the resistor wires were bent around into a floppy loop whose size and shape - and therefore inductance - is not very well controlled. The very small inductance of the resistor body could easily become lost in variations caused by small accidental movements of the wires. It is also an experiment that cannot be repeated, because of the conductive paint.

If I'd found time at the weekend, I would have made up a little plate like W4ZCB described. The N2PK VNA uses a three-step calibration with open, short and 50R standard loads. For this jig, I'd have had to start with the open-circuit connector spill, followed by a solder-blob short, and finally by the best solderable 50R load I could make (probably two 100R chip resistors in parallel). Then I'd have cut short the wires of the test resistor, and soldered that in place on the plate for the actual measurement.

But unfortunately the whole weekend timed ou

Maybe he does have something not listed, maybe you should have asked him directly.

Also, nobody the fuck asked him, nobody has to, this is a news group, get used to it. You asked a stupid question and you got what you deserved.

Nobody outside of broadcast calls them 'shortwave transmitters' anymore, and if you're really looking for a shortwave transmitter it's doubtful that someone posting his 'for sale' list of ham equipment has one sitting in the back of his garage that he didn't waste time typing one more line about because he didn't think it would sell.

So, go the fuck back to CB.

Um...let me give you a "english translation" for the "shop talk". The word
"alligator" means a pretty hefty power level. The "2 meter" part means the
2 meter amateur band. Most hams know this means the 144.000 to 148.000 mHz
range of frequencies. "What would the meters display?" Well, that's your
question since its pretty clear you don't have what I'm interested in.
But, one possibility I'd be interested in would be a homebrew job that had
at least grid and plate current panel meters, but a builder could have put
in a rotary switch to connect one panel meter to different parts of the
circuit. Ever hear of a D'arsonval movement?

4028. Wanted: Power Supply for TR-4C

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-12-08 21:31:24 UTC
From: KA9S-3_Jeff <ka9s3@comcast.net>
Message-ID: <sfadnQ4GvPFG7yrcRVn-gA@comcast.com>
Source record: 21712
Cross-posted to: rec.radio.amateur.boatanchors,rec.radio.amateur.equipment,rec.radio.amateur.homebrew

Wanted - Cheap - for Drake TR-4C: broken AC-4 or AC-3, or home brewed power supply, or modifiable power supply by other manufacturer, or interesting power transformer.

I want to power up a Drake TR-4C I picked up. It did not have a power supply. The price an AC-4 power supply brings today is more that the transceiver is worth. Are there more radios out there than power supplies? (Kind of like there are more horses asses than horses). Are the high AC-4 prices a function of scarcity or what?

I've looked at the schematic of the AC-4 and decided that it's not rocket science. I'm not putting together an "original" collection of Drake equipment and I don't need the power supply to fit within a MS-4 speaker (which I don't have and don't need). So - I think I have some economically appealing options.

- I could repair a broken AC-4, AC-3 as long as the transformer is OK.

- Home brew power supplies do not scare me.

- It's possible power supplies for other rigs could be adapted to work with Drake gear.

- I could build my own homebrew power supply. The critical component would be the power transformer / transformers. (There are many power supply designs that would work).

Here is what the power supply needs to do:

Input: 117 vac
Outputs: (12.6 vac @ 5.5A), (650 vdc @ 300mA average - 500 mA peak), (250 vdc @ 175 mA), (-45 to -65 vdc for bias)

If any of you have something to sell me that will get me there, please let me know (with details).

Thanks Jeff - KA9S

The trouble with the 98% of USA citizens who are not aware of the existence of the rest of the world, or the damage caused by world-wide indiscriminate use of their weapons of mass destruction, is that they are far too childishly patriotic. They natuarally believe their own distorted, hopelessly biased propaganda, fundamentally generated by their international oil and energy, atmospheric-polluting companies.

Iraq, Palestine and other middle-eastern and central Asian countries are heading, slow-motion, towards another Vietnam, Cambodia and other places left poisoned and in ruins. Your boys in the armed services will return home, not necessarily all in black bags, but in the form of many thousands of unemployed hillibillies, drug addicts, detested outcasts of society.

But it need not end in that way. You are all-powerful and rich. Just find some teachers and educate yourselves before it's too late. For everybody's sake on this small overepopulated, underfed Earth.

You could probably use a Heathkit HP-23 or one of the A/B/C
varients. The Heath's voltages are higher than what you spec.

HP-23's are about $50. There's almost always one or two on eBay.
I saw one go for $30 at a hamfest this spring.

An 'all in one' transformer might be difficult to find ; however since it is
assumed the unit is in a separate enclosure ,you can implement the power
supply unit with up to 4 separate transformers which no doubt can be found
at various ham fleamarkets .
The biasvoltage can probably be obtained through a separate diode and zener
voltage
circuit ,using the transformer supplying 250V @175 mA ,which would enable
you to implement with a maximum of 3 transformers.
Good luck with your quest.

I'd had problems w'em all, so for me it's a real crap shoot. Lately, however, FedEx seems the best, as long as I don't use "home delivery". I had a package that, for several days, the tracking indicated "attempted delivery". I had been home (work from home) and I KNEW that no one had attempted delivery. Plus, they had left no notes. Of course, FedEx people didn't believe me, they believed their computer. Finally, when they were going to send it back to the shipper for "exceeding delivery attempts" I insisted I talk to the driver that was attempting the deliveries. They said that wasn't possible, that he didn't carry a phone and he'd try one extra time. He called later on his phone, asked if I could meet him somewhere. By this point I was willing to do most anything. When I met him he told me that his section was having trouble making all of their deliveries so his boss was telling the drivers to mark bunches of their packages as "attempted delivery" at the start of each morning.

I had a USPS package, arrived with big "FRAGILE" stamps all over it, and a large, perfect boot impression in the middle of the crushed-in side. I kept the box, it was so funny.

UPS mis-routes about 2/3 of the packages to my address.

I don't know, I'm 'notgonna,' with n's.

Why is ass fucking the first thing you resort to as a weak, immature and somewhat perverted attempt at an insult? Is ass sex something you think about a lot? If you've been abused in the past I suggest you seek help instead of venting on news groups. If you're an abuser I strongly suggest you seek help and quit trolling for victims on news groups.

Once you get out of junior high your level of insult sophistication may improve, but I seriously doubt it, you're not even capable of finding adequate ways to buy the gear you're interested in or even using the correct terminology to find it in the first place.

Go the fuck back to teevee, I think even CB is beyond you.

In addition to the voltage being MUCH higher than the Drake likes, the Heathkit HP23-series supplies couldn't begin to provide enough plate current for a TR-4C! Peak current consumption of, say, an HW-101 or SB-102 is 250 mA. The Drake draws twice that!

I have been inside our local USPS office during mail sorting. Packages came off the truck on big carts, and they would line up smaller carts (the size and type you might see for laundry in hospitals or hotels, the big cloth sided ones). The packages would get tossed like basketballs, from the big truck cart into the appropriate smaller cart for further sorting and delivery. "FRAGILE" on the box doesnt mean anything. Actually, something fragile is more likely to be light, and can be thrown father, while something heavy may actually cause them to have to walk over to the cart.
I asked the USPS worker about it, as a "fragile" box flew through the air, and she said, "we tell people to pack their stuff right, if they dont its too bad".

>experiment that cannot be repeated, because of the conductive paint.

All noted and good, Ian. The thread had become (in my estimation)
one of those "intellectual exercises" that don't have much real
practical significance. :-)

Of course the resistor lead contribute some inductance. In fact, most of it. However that inductance is directly calculable based on old, available data. What remains is the resistor body itself. A very quick approximation of that body would be to get a scrap of kitchen aluminum foil and wrap it tightly around the body with the overlap tight around the leads to make contact. [won't make much difference because the body, being larger in diameter than the leads, will have much less inductance than those leads]

Some tubular film resistor constructions use a small metal end cap to "grab" the leads and also bond to the substrate material. That adds a shunt capacity component across the whole thing and the equivalent model starts becoming busy with long equations describing it. In the analyst's real world, the actual (external effect) inductance is slightly less because the series resistance is distributed along the "inductive" spiral...and, as has been pointed out, not even along the body. One can go nuts on that intellectualism...which wastes time that could be spent on a project's other things. Time we ain't got in large doses, prescribe well. :-)

>100R chip resistors in parallel). Then I'd have cut short the wires of
>the test resistor, and soldered that in place on the plate for the
>actual measurement.

That's the basis for the minicomputer-network-analyzer systems that debuted in the early 1970s (HP in 1973?). The open-short-characteristic-termination will "calibrate-out" the test equipment itself through the numerical results calculated within the computer, leaving only the characteristics of the device under test. Ideal for actually seeing (HP had a small CRT Smith Chart display for a quick look) the effect of the device on the applied circuit.

I haven't looked to see if Agilent (what HP test and measurement division became after Big Business of computer product take-over of HP) has now for App Notes. I have some of the original free App Notes from HP (back when HP was HP...:-) and the going gets tough through all that four-port math. If someone else has gone the same route and put it all into some software/firmware to let the casual hobbyist go at it easily, then good all around. That kind of metrology gets heavy indeed.

For practicality in the homebrew labor-oratory, several different-frequency measurements of a device should be good enough. That yields the complex data from which an approximate model can be derived. Very approximate. But that is normally good enough for general narrowband RF circuit work of the amateur radio kind.

One problem is that some folks, on seeing the results of careful measurement on one resistor value of one physical size from one manufacturer will now adopt that to apply to ALL film resistors regardless of value or source of manufacture. Probably the same folks will look at a "coil" of wire and think "inductance!" while neglecting the fact that straight wire (not to mention its return path) will have inductance as well. :-)

Hello,

I have four radios in my vehicle, all with remote speakers (unpowered) that are fairly close to each other. It's confusing sometimes when squelch breaks, to identify which radio is active.

I'm wondering if there is a way to rig a circuit, so that a small LED light can be inserted into the speaker wires somehow, so that the light illuminates when the speaker is active.

Thanks for any help,

Mike

I would really have to question that a Power Supply for your Drake could
be made cheaper than buying one unless you find enough fools to give you
all the parts and they pay the postage to ship them to you. You should
be able to find a good used AC4 or $75 and an AC3 for even less. A
Heathkit should work with minimum modification put they seem to go for
about the same amount. Try a Swan or a Galaxy but I expect they will be
just a little cheaper but not much. I believe the rule is about a $1 a
pound. Just don't look at the Collins stuff.

I might be able to find you a Transformer but it will cost you $25 plus
$15 for postage.

Mike,

I do not know what radio mfg. or models you are using, but I believe that one of the GE MASTR heads had an option for an LED (or bulb) to perform such a function.

Greg

Thanks Greg, I'm using Radio Shack remote speakers. They're very
small cube shaped speakers with mono mini-plugs on the end of
about a 10' wire. As I said, they're unpowered. I just have them
plugged into the aux speaker out connection on the radios.
Can you tell me more about the GE MASTR units?

Thanks

I use to operate a GE MASTR II VHF (110 watt model) mobile for 2 meters in 1980s and early 1990s. When I traded cars, I took out that big trunk unit, but never installed it in my new car.

Kevin Custer, K3KKC has a very good web site on the MASTR II units (many have been converted for repeater usage) as well as other GE models. In fact, my old repeater club installed an old retired GE MASTR PRO (had a tube final section) thirty years ago .. that worked quite well .. once WB9GGO (sk) fixed many of its little problems (like cracking the tubes every ten minutes) !

The MASTR II has a RX squelch logic signal (RUS) that is normally present at the remote head. With that logic you can turn on a small LED or 12 volt bulb when the receiver is unsquelched (useful if you have the speaker volume turned down). GE had an option which was a resistor, bulb and bracket for mounting in a spare "window" on the remote head and attaching to this logic line.
RUS is the RX squelch logic signal for the MASTR II is available at J904-8 (RX Unsquelched Sensor). The MASTR II also has another signal called "Carrier Activity Sensor" available at J901-16, but this signal usually not used (results in increased chopping of weak signals).

You may have this logic present in your radio, but it will take a schematic and/or service manual to trace it down and check how the logic is presented for usage.

Greg

Thanks again Greg for the info, but I guess what I'm looking for, is a way to trigger the LED with just speaker level voltage. I don't really want to run a separate wire to the speaker or tamper with any of the circuitry inside the radio.

This doesn't sound much like rocket science, although it strikes me as more hassle than it should be. First, you want to sample the audio with a high impedance -- probably an op amp would do here. Then, you rectify the noise and feed a comparator, or maybe just a transistor. Use that to drive a LED.

The actual mechanics of getting a wire to sample each speaker and then placing an LED near each radio, or in some sort of arrangement that helps you know what radio, seems to be as much of a hassle as the electronics. Maybe you have a box that connects to each radio and then from there to the speakers. If you make each LED a different color you would eventually associate the color with the radio. Might work better than getting used to the position if the LEDs are all close.

Interesting problem though. Practically all of my radios have either an LED or an indication on the LCD that the squelch is open. Could be because I tend to favor Icoms. But it doesn't seem to help remind me to engage brain and think about what radio is talking before I pick up the mike!

G'day Art, don't worry about BOG (as he is also known), he has a bee in his
bonnet about the "proper" use (i.e. traditional English) of the English
language - he is always trying to get people to use "metre" rather than
"meter" when referencing frequencies or lengths. He really is a tool, but
most people just ignore him.

John,

I mostly agree with you, but I have seen a lot worse in these groups,
and you have to give the guy credit for being truthful with his identity.

And just to keep it somewhat on-topic (I can't imagine how to do so with
this many groups), I've used a similar product that I got at Home Depot
(cheaper there), and I was AMAZED at how well it works, exactly the way
that RBR mentioned. When I'm digging around behind my computer, or
amplifier, or my HF rig, looking for the right jack, etc., it it 100x
better than using a lamp or handheld flashlight. I'm farsighted and
have to use glasses for anything closer than 3 feet, and bright light
really helps. Aha! My post is relevent! At least, to other old guys
like me.

Disclaimer: I don't know W7RBR nor anything about his business.

73,
Dave

I'm just going to throw this out for thought....

Try using an audio transformer as a current transformer into a high-efficiency LED. Break the wire to the speaker and insert the low impedance winding of the transformer in series. Connect the LED to the high impedance winding with an anti-parallel diode (1N4004, say). Use maybe a 10:1 turns ratio transformer (100:1 impedance ratio) from Mouser, Digikey, or Radio Shack.

If one assumes 50 mW output power into 8 Ohms, that is about 80 mA of current to the speaker. The transformer makes it about 4 mA into the LED (the 1N4004 conducts in the opposite direction). I think 50 mW is a very low estimate for the amount of audio you need in an auto. If the LED burns out, use a higher turns ratio transformer.

The LED will flicker with the audio. The louder the audio, the less flicker and the brighter the LED. Conversely, if the volume is low enough, the LED will barely flicker and be mostly off.

Anyway, just an idea.

Good luck.

There's a very nice little program at:
http://www.dl5swb.de/html/mini_ring_core_calculator.htm

It has probably the most complete built-in library of cores and
dimensions, and does just about everything.

It doesn't contain Q data, but these only exist for certain cores, and
no calculation is required anyway - just read the graphs, which are on
the web.

Silvio -

The color of conductors are consistently assigned to a specific "pin" on a microphone connector. I have seen identical microphones very, due to different cable sub-contract suppliers.

The color codes are not shown in the Icom SM-8 manual, just the pin assignments (for various radios)
http://www.icom.co.jp/manual/external/transceivers/SM-8.pdf

The SM-8 does have an internal pre-amplifier, powered from the Icom transceivers (at the mic connector). A VOM and wire tracing may be the best approach

GREY
> WHAT PIN NUMBERS DO THEY GO TO ....some one please help me
.....73s
> silvio

On my mic (serial #14785), they go like this:

1 - white
2 - black
3 - blue
4 - NC
5 - red
6 - brown
7 - braid
8 - NC (center pin)

As you can easily see, there doesn't appear to be any hard/fast rule to
the color scheme or to the number of conductors.

Sorry, Len, I stand to be corrected (no doubt) but surely this way of
shorting the ends together is going to make matters much worse? Aren't
you going to end up with a significant amount of capacitance between
your outer foil and the inner spiral of resistive film? Isn't that
going to just throw another complex variable into the mix and probably
completely change the resistors SRF?

Has anyone carried out any tests to compare conventional spiral
elements with the 'doubling-back spiral' types that claim to be
"non-inductive"? I just wonder if that doubling-back of the resistive
element to 'eliminate' inductance is as effective as it's made out to
be.

And of course, the connections to the RJ45 are different across Icom radios,
too. Hopefully, the manual for *your* SM-8 should show what color has what
function. You need to mate that with the manual for your radio.

Typo on original post, and I see that Anthony Fremont opwned up his SM-8 to provide you the pin to color assignment.

BUT, the color of conductors are NOT consistently assigned to a specific "pin" on a
microphone connector. I have seen identical microphones very, due to different cable sub-contract suppliers. Please check (and confirm before soldering) .. especially the +8 VDC lead which can cause damage to the microphone and or radio if not properly conencted.

The color codes are NOT shown in the Icom SM-8 manual, just the pin assignments (for various radios)
http://www.icom.co.jp/manual/external/transceivers/SM-8.pdf

Not just tables/equations but a FREE downloadable program
(two in fact) from Micrometals in Anaheim, CA. To get to the
download page either click on the bottom screen icon of website

http://www.micrometals.com

or enter direct at

http://www.micrometals.com/software_index.html

The smaller file size program will produce some Q and self-
resonant frequency information but Micrometals' famous Q
curves section of their printed catalog is favored by designers.

If your cores have no identifying iron powder "mix" then you will
have to resort to basics of trying to find that out in order to use
the Micrometals' programs (which use their "mix" information
directly). Q at a particular frequency band of interest is very
dependent on the iron powder mix.

Note: I have no relationship with Micrometals but have used
their products and information for three decades applied to both
work and hobby projects with excellent results. Most of the
original Amidon packs used both Micrometals toroid forms and
their literature (reprinted with permission).

Yes, Paul, it is effective...but "effective" is relative on how you do the "doubling-back" winding. You can do a quick comparison yourself by sacrificing some magnet wire for a particular former. Cut two equal lengths of the same magnet wire. One of them is bent into a close-spaced horseshoe. Get a former, any kind, although a toroid form will be more practical for connections.

Wind the former with the unbent wire, close-wound, counting the exact number of turns. Measure that and record it. Unwind it and use the same former to wind the same number of turns using the bent-in-two piece of magnet wire, again close-wound to get the spacing very close to the first trial.

With an axial-lead former you can start with the bend at one end and work towards the other as if you are winding two wires at a time. The end of an axial-lead former presents a small problem since both ends wind up there...therefore a toroidal former is more practical to do this test. [visualize that compared to first trial] Measure and record the second trial with "doubled-back" winding.

The difference between the two trial measurements is the "cancellation" of the inductance by confusing the heck out of the poor magnetic field (it isn't sure which way it is going...one can say "it is all fluxed up").

Are those measurements useful for anything? Not really. It proves a point in a formal lab class on the basics of inductances. Trying to use a resistance-wire helix structure at MF or higher is not the best of techniques (actually rather foolish). Secondly, there's all sorts of components of an equivalent model of the "doubled-back" sort of winding and one will wind up in a psychiatric ward on trying to sort them all out. Add to that the variation between manufacturers on the physical shape, resistance (or even film) path length, winding method, and so on and the number of variables gets very high.

Practical way is to simply measure the whole device at the frequencies of interest and be done with it. If the catalog information doesn't state

a device is useful at RF (or whatever), then do NOT expect it to be good for anything but DC to audio frequencies.

I've seen where a 5 Watt power resistor was effective as BOTH a DC dropping resistor and an RF choke with the resistance winding forming an inductance. All well and good until another manufacturer's 5 Watt wire-wound resistor was tried...and didn't have the same inductance, resulting in marginal "choking." Same specs and conditions for both wire-wounds...which did NOT specify any inductance characteristics.

Ya takes chances, ya gets unusual results.

>completely change the resistors SRF?

Paul, don't kick yourself after reading this, but shorting out the body
with foil will put a conductor in contact with BOTH ends of the
resistor body. :-)

I mentioned that only in passing since it isn't necessary to do in order
to find out anything significant.

Finding a "self resonant frequency" involves doing several
measurements of the total R, C, and L of the device, finding the
complex R and X at each, then plotting that (a Smith Chart will do
it nicely) to see the skew shape of the curve as compared to a
perfect resistor (a single point on a Smith Chart). You will have to
work out the SRF yourself based on that information; that is going
to vary with each specified R value, film type, and the kind of laser
trimming (or whatever) is done to get the DC/low-frequency R value
precise through a film spiral or gouging or whatever. Not needed.

If you just measure the device with a bridge/instrument yielding the
complex impedance or admittance, you just apply that to the
circuit taking the device and be done with it. You will have to allow
for some adjustment in the circuit itself to compensate for the
device characteristics (whatever they come out to be).

An analytical model of the resistor is an R component in series
with an L component (due to any spiral of film, if any, plus the
length/diameter of the resistor body), but that has fringing capacity
between the ends of the leads inserted into the body...that capacity
being in parallel to the series R-L connection. You can estimate
that and do a paper exercise to see the effect for jollies...or just
skip it, use the device measurements to base the overall model as
it applies to the circuit and go on with the project.

The effect, if any, is going to be minimal with 1/4 Watt or smaller
resistors at VHF on up to low UHF bands. Nothing to worry about
provided the leads themselves follow the usual "short as possible"
rule.

One can go nuts on the intellectual paper exercise and about all
it is good for is mumbling-bragging over glasses at the local pub. :-)

I have a Sirius sat radio and I like it a lot. The big problem I have it use's a FM modulator to send it's output into my car radio. While that's fine if the frequency is clear, as I travel I bump into FM stations on the same frequency and it bleeds through. I know they sell switches to divert the car radio's antenna to either the normal antenna or the Sirius radio. The problem is I don't want to rip my dash to take out the radio to make that connection and was thinking that a little more power out on the FM side would help a lot. Does anyone have any ideas? A small amp for the FM out comes to mind. Anyone have any experience with anything like this?

If possible select an FM frequency between 88 and 92 MHz. This spectrum was
originally for LPFM, education stations. Most new stations are less than 1
kW, many in the 100 watt class. Easy to find a spare channel in many areas.

I hav a dds daughter card from the njqrp club
and the picel from amqrp.

they work together to make a dds vfo.

I looked at it on my hp 140T/8555 spectrum analizer
and I could not see any spurs on my analizer.
(not exactly the best combo for this job realy designed for microwave).

amqrp has the schmatics online at therir site.

Good Luck

> Can the Sirius radio be set to a different FM frequency?
==========
If your Sirius Radio has an audio output and your car radio a cassette player ; you will be able to either homebrew or purchase an audio cassette shaped transducer with an audio input ,which you stick into the cassette player , such that by "playing the transducer" you can listen to its audio input being the audio output of the Sirius radio.

That would solve your 'free FM channel " problem , although perhaps with a somewhat reduced sound fidelity compared with the FM radio route.

A long time ago I have seen articles for homebrewing the above transducer. It is a coil inside the cassette placed at short distance from the cassette players 'head' ,the coil being fed by the audio signal source. It is also a simple way to connect a ham radio transceiver to the car's loudspeaker system.
I thought that Ratshack might sell the above type of transducer.

Hi Jeff,
Wow, what a mess of replies you got, but nobody offering to sell you
one.
I have 2 possibilities:
1 - what appears to be a hombrew "repackage" of an AC-3 on a small
chassis. It looks like the components are from an AC-3. I powered it up
some time ago to ck voltages, seemed OK, but I didn't put it to any rig.
It needs am AC cord, and has a female jack for outputs.
2 - a stout HB supply in a covered chassis like they used to put audio
amps in. I used this for a while with a T-4X. It has a terminal strip on
the back, and a cable with the proper Drake plug.
I can take digipix of both.
$25 for #1
$50 for #2
plus postage

A lot of amateurs confuse powdered iron with ferrite. They're very different materials, and each is best for particular purposes. MicroMetals makes powdered iron cores. A number of other vendors, such as Fair-Rite, Magnetics, Ferroxcube, Siemens, and others make ferrite cores. Amidon sells both, with powdered iron part numbers beginning with T and ferrites beginning with FT.

There are many types of powdered irons and many types of ferrite. It's vital that you choose the type which is appropriate for the job. Once you do that, the design of the inductor or transformer is usually pretty straightforward. But if you choose the wrong material, you're likely to end up with a very poor component.

Most or all the manufacturers I mentioned have web sites that provide a lot of information about how to choose the right material for a particular application.

radio.

Until recently, all of the sat radio boxes came
with a fake cassette of this type. Since cassette
players have vanished from new car radios, the FM
modulator is the answer these days.

I too have the interference problems using the FM
output from my XM. Fortunately my car radio still
reads cassettes. We have strong FM stations every
400 kHz around here, in some cases stations in the
Balto/DC area are just 200 kHz apart.

One of the serious problems using the FM approach
is that one must set the audio level far below
what you get from over-the-air FM stations. FM
stations process their audio to be LOUD, yet do
things to negate the 75 us preemphasis curve.
Your XM/Sirius FM modulator doesn't have all that
fancy processing, so you may have to set it as
much as 10 or 15 dB lower in level to avoid
overdeviating.

The only really good way for sat radio is a direct
audio connection of some type.

The Sirius radio has 88.1, 88.3 88.5 and 88.7 preset out. So I ca switch it at will.. But the problem is I have to dig around behind the radio to flip the switch.. and in some cities they have all those frequencies in use. It don't take much to over ride the modulator. I'm going to see if I can maybe make an antenna to connect to the Sirius radio to bring the level up a bit and get it closer..

I could us one of them cassette devices, but that's just another piece of equipment hanging off the front of the radio.. I already have a hf and a vhf radio. Not to mention the normal car radio.. One would think I had enough to listen too.. LOL

4099. help: repair to VHF marine radio

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-12-12 17:46:01 UTC
From: Larry Gagnon <lagagnon@fakeuniserve.com>
Message-ID: <hq0pr0hvv22li9a9r0akp5nhrvtcufv4t9@4ax.com>
Source record: 21684

I am attempting to repair a Midland Model 78-100 VHF Marine Radio for a friend. I have basic radio electronics knowledge, some troubleshooting skills, a 275MHz scope, VHF sig generator, freq meter, RF power meter, a working VHF radio etc, but am unable to locate the problem.

Symptoms are: completely dead on receive and transmit on all channels, but unit powers up good, all power supply circuits and voltages are good, display and frequency display circuitry are good, no detectable cold solder joints nor saltwater corrosion anywhere, power to all chips is good.

I first suspected the PLL circuitry (due to its being common to RX and TX), but signals coming out of the PLL, prescaler and VCO chips appear ok.

Any suggestions as to where I might start looking would be greatly appreciated.

The Vector Network Analyzers yield the complex-quantity Z or Y
directly...which is a wonderful thing for really detailed design and
checking to see if a part/device/etc. will fit an application.

A very few "RF Bridges" might do that but their upper frequency
limits are rather limited for venturing into the high end of HF and
certainly not VHF and up.

For the hobbyist lacking a VNA, I would suggest the neat little
LC-Meter from AADE. I have one and find it extremely handy
for winding lots of coils (particularly toroids) without firing up the
VHF Q-Meter now rather on its last legs and needing calibration.

I don't worry about the "intellectual exercise" sort of things, such
as "self-resonant frequency" of a resistor. That is mainly up to the
lead length rather than any spiral of resistive film in the resistor
body. The circuit to receive such a resistor has to be calculated
to take an _estimate_ of the residual/parasitic L or C with, if the
need is critical, some sort of trimmer to "tune out" that L or C.

Case in point at HF: Bandswitched coils for an old multi-band
"communications receiver" took care of tolerance variations in
those coils either by using adjustable powdered iron cores or by
individual trimmer capacitors (usually compression micas). Some
of the same method can be applied to higher frequencies, such as
a rotary ceramic or piston trimmer cap or turns-spreading/
-compressing of a toroid or solenoidal core coil to adjust the L.
The point I'm trying to make is to prepare ahead of time.

That preparation is anathema to some who just like to grab parts
and stuff them together based on old rules of thumb or imprecise
nomographs, then "hope for the best." One can get away with
that at lower HF most of the time but that gets tougher going up
in frequency. Analysis models will take care of finding a spread of
part tolerances and what to do about trimming them out. That's
all paper work and - unfortunately - shunned by many. One excuse

is "I haven't got the time!" However, bad preparation will have the TIME spent in trying to adjust something, taking comparative measurements, etc., is usually takes more time than doing the initial paper work on analyzing the circuit.

As to measurement methods with different bridges, there's lots of texts available to cover that, most of them old ("old" being at least 30 years back, heh heh). General Radio wrote up the circuit details on their old RF bridges in fine form, sometimes including that in their owner's manuals. Problem is, that sort of thing takes even more skull work to make sure of accuracy...plus planning on how to calibrate it once it is built. [ain't no good if it reads wrong or has improper calibration]

Some of the simpler bridges are the "substitution" variety such as the extremely portable RX Noise Bridge (noise excitation for the RF source makes it portable, it works fine with a known frequency source too). One arm has a calibrated R and C in parallel (the "known" side) while the other arm has the unknown with half-value of the calibrated C duplicated across the unknown. It basically reads admittance when balanced but that can be recalculated to impedance with a handy scientific calculator such as the HP 32 SII or the newer 33 model (each does a single-key complex inversion). The simplicity is what makes it good; symmetry in physical construction is easy to achieve, that increasing the accuracy of the little instrument. The known arm of the bridge can be calibrated with some of the newer digital capacitance meters that go down to picoFarads of resolution, the R part of the known arm calibrated with an accurate DVOM. A dual carbon/metal film potentiometer wired in parallel will reduce the internal distributed inductance of the varying position of the wiper arm.

One problem of those simple bridges is that one spends a LOT of time taking readings and then converting them to useful number quantities. A VNA using a microprocessor can do all that math for you and at many frequencies in an eyeblink. Reduction of TIME spent in getting data is very powerful with the VNA. An extension of that would be a Smith Chart presentation on-line (as the fancier HP analyzers had/have) for direct visualization of what the heck is going on inside something. Hobbyists are always short of time. :-(

IS the crystal in the PLL "ON FREQUENCY"? IF it is way off - but still oscillating - due to some defect, that could cause the problem. The voltages and such may "appear" ok, but the crystal won't allow "ON CHANNEL" signals to come or go. Check your frequencies and such. The other thing common - is some of the audio stages. Are they working? How about the function switches, maybe not making full contact - especially if there is a radio/pa switch or something similar. They could create similar problems. Those are the other common things aside from the Power Supply legs. Microphone wiring is sometimes common also, a broken wire or two, won't allow it to transmit OR audio to come through to the speaker. I don't have any info on this radio to be more precise.

Lots of luck.

Actually, we are all too aware. Even today, the foundation of our country is based on immigration. Point to any one schoolchild ignorant in geography and histor, and he or she will point to a grandparent from the old country.

or the damage caused by world-wide indiscriminate
> use of their weapons of mass destruction,

We've only deployed two weapons of mass destruction in anger: at Hiroshima and Nagasaki. True, we've made quite a few atmospheric and underground tests since then, but *none* of them have actually been used against a target. And as far as I know, even though the US stockpiles chemical weapons we never even considered germ warfare.

Or are you speaking merely of the damage caused by deterrence? All that managed to accomplish was the quiet collapse of the Warsaw Pact.

is that they are far too
> childishly patriotic.

True, we teach patriotism to children, and hopefully this childish patriotism becomes an adult version based on government by consent of the governed. The true test of this is our continued willingness to pay taxes.

They natuarally believe their own distorted,
> hopelessly biased propaganda, fundamentally generated by their international
> oil and energy, atmospheric-polluting companies.

Sorry now. The last propaganda I have ever heard of has been generated by speechwriters in the Republican, Democratic, Libertarian, and Green parties. I don't notice the speechwriters being in the pay of multinats.
>
> Iraq, Palestine and other middle-eastern and central Asian countries are

> left poisoned and in ruins.

Not our fault. There was conflict and chaos enough caused by regional despots, absolute monarchs, and fanatics willing to see the human race extinct rather than see even a single person free of the yoke of thier

own religious totalitarianism. Our involvement is slowing this
downhill slide, not exacerbating it.

Your boys in the armed services will return
> home, not necessarily all in black bags, but in the form of many thousands

of unemployed hillibillies
Hey, those hillbillies were unemployed before they joined the army to
give themselves college educations and their families a better shot at
the middle class.

, drug addicts,
Soldiers now get therapy as part of their health package. Battle
fatigue is now a recognized illness that even the most gung-ho general
would fail to confuse for cowardice. Further, the Vietnam era US army
had just as huge a drug problem as the rest of society. In modern
times drug addiction rates by veterans are less than our population as a
whole.

detested outcasts of society.
Only because we treated them that way when they came home.

>
> But it need not end in that way. You are all-powerful and rich. Just find
> some teachers and educate yourselves before it's too late.

For everybody's
> sake on this small overepopulated,

A canard. The Western democracies are actually experiencing a
population decline. China and India are presently undergoing
industrial revolutions that are helping greatly to stabilize the
rate of population increase. Africa and South America are still
big problems, caused by persistent poverty, tyrranical governments,
and tribalism in lieu of the rule of law.

underfed Earth.

Another canard. The hunger problem is not caused a lack of production
capacity, but from the inability of much of the people to find work to
earn money to buy the food produced by their neighbors.

Capitalism itself causes
uneven distribution of resources, but as the world has seen, any other
system acheives worse results. Dorothy Day said it best that to tie
worth of a person to usefulness was to sin against the inherent dignity
of that person.

If we had a worldwide welfare state, our world could support a hundred
times its present population.

This is the one instance where the Roman Catholic Church actually has it
right.

4106. OT EMI problem with stove and internet connection

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-12-12 22:19:12 UTC
From: default <none@defaulter.net>
Message-ID: <7edpr09ucaqbb457bqknkaefqbtkccasv6@4ax.com>
Source record: 21690

My electric stove is talking to my modem, resulting in the modem dropping its speed back or losing the connection (dial up). I can turn any burner on high and everything works. Turn the "infinite" control to a midpoint heat setting and the modem goes out to lunch.

The controls are primitive types with a heater and bimetallic strip inside them (I disassembled one to fix it). The contacts appear to be real silver.

The only place the modem and stove come together is at the CB panel they have independent circuits up to that point.

Modem line is 40 feet of UTP cat 5 up to the phone connection box. (added the twisted pair in an attempt to fix the problem) The lines are >10 feet apart everywhere except the CB panel.

Phone box and power share the same earth ground. I lifted the power connection and saw no unbalance (0 VAC) between ground and neutral with the stove cycling.

Any burner on the stove causes the problem. The small one is 600 watts the oven 2,000 watts. 240 VAC to the stove 120 to the outlets.

If I turn my stereo on (same circuit as modem and computer) and crank the volume to uncomfortable levels (unless of course I've had a few home brews) the problem goes away (and no my perception isn't at fault . . . but, truth speaking, in that condition most problems do go away)

Stereo PA has a very stiff power supply >100 joules with HF bypass photo flash caps and polystyrene layered caps. Problem only goes away with bass turned up and continuous music source, or large bass transients. (floor shaking, teeth rattling, bass)

So far I've added twisted pair to the phone connection (40 feet), a toroid to the (external) modem's wall wart transformer, and a toroid to the phone lines - in all cases for common mode rejection - not around each line.

Interested in hearing from people who have solved this problem, or just anyone with an idea of what to try next. Stove is easy to get to, computer 120 VAC easy to access, power panel less so.

Short of staying inebriated and playing the "Sheffield Drum Record" or "Lisztronique" over and over . . . (I'm willing, but my wife has a problem with that approach)

Seems to me that you may have either (or both) of two problems: a
brief voltage drop when the stove heating element is switched on
(perhaps enough to "brown out" the modem's power supply) or a burst of
RF noise when the contacts open and close.

I'd guess that the stove heater element is drawing a pretty hefty
surge when it's first turned on, before it heats up and its resistance
increases. This might result in a one- or two-cycle voltage-drop
brownout which affects the whole circuit and may show up in other
circuits as well... it'd depend on the quality of the house wiring and
of your electrical service connection.

If this is the case, you might be able to correct its effect on the
modem by using a UPS. Unfortunately, most consumer-type "UPS"
products are actually SPS (standby power supply) designs, and they
don't turn on their inverter and supply power to the device-under-load
until there's been a brownout or power loss for a couple of cycles.
This might not be fast enough to keep your modem happy.

If your modem uses a 12 VDC supply from its wall-wart, you might be
able to fix the problem by using a "12-volt" gel cell as a power
supply, with a well-regulated DC supply of 13.4 - 13.5 volts to keep
it charged up. If the AC voltage sags for a moment, the modem
wouldn't even notice.

Another possibility is that it's a burst of RF noise, carried in
differential mode on the power wiring, when the bimetallic switch
opens or closes. A common-mode ferrite on the wall-wart cord wouldn't
help with this, I think. You could try either of two things:

- A differential-and-common mode AC-line filter, at the modem. Some
AC power strips incorporate them, and you can get ones with better
filtering/attenuation in sealed metal cans, with either wire-lead
or push-on connectors (Corcom and others make 'em, and electronics-

surplus stores usually have some).

- A snubber, at the stove itself (the source of the problem). The snubbers I've seen are usually caps of .1 - 1 uF in capacity, in series with a few ohms of resistance, in a flame-resistant plastic encapsulation. They're designed and rated for use directly across a power line (I believe they have "X" and "Y" rating codes).

You'd probably need to have one of these wired in across the line, either just before or just after the bimetallic switch. Probably the sort of thing which should be done by a licensed electrician.

A battery-powered-modem-with-float-charger-backup might also be a good way to deal with the problem if its cause is RF noise on the phone line. You could add additional filtering of the DC before it reaches the battery, to keep it well out of the modem's supply.

Hmmm... another thought. You might want to check the arrangments by which the phone lines are safety-grounded at your building's MPOE. If your phone line's grounding system is connected to the same ground rod as the power (which it probably is), and if there's any amount of "ground bounce" when the stove load is turned on or off, and if there's some amount of current leakage in the phone line protection system (e.g. if it has old-style carbon-block spike-eaters, or if there's a dirt-and-moisture current path) then it's perhaps conceivable that turning the stove on and off might result in a momentary voltage spike on the phone line due to this common-ground-path setup.

Thanks Dave

I do have a common ground for phone and AC at the box, I figured
lifting the ground and watching with a scope as the stove cycled ruled
it out. I can lift it at the 'puter end and see what happens.

Phone has a MOV protector and it was put in 5 years ago. All wiring
looks clean and AC and Phone are outside a few feet apart with no
common path (and problem doesn't get worse with rain etc.)

You did give me two ideas I hadn't thought of. Snubbers on the stove
and a battery isolator on the modem. I think it is 12 AC but the case
comes apart easily.

Make that three - brown out, my AC line runs 106 to 108 most days. I
don't complain to the power company because I figure it probably saves
me money in the long run (power bill ~$20 month for year average but

I'm frugal too). I do have a variac and can wire a boost transformer to the modem if need be. The three terminal regulator in the modem runs hot so I guess I developed a blind spot about the low voltage possibility.

Thanks again

An electrician? perish the thought. The stove is just a big metal box with a few switches and resistors in it. Besides it can be unplugged or switched at the breaker. (how I normally work on it)

You've not said whether you have a schematic but if so, look for the TX/RX change-over circuitry. If that is not working properly it could be disabling both parts of the transceiver. Commonly that kind of low-level switching is done by biassing a diode in the IF region or changing the gate voltage on a MOSFET. An ICOM ham rig that I repaired recently had a common 8V line switch to do just such a job.

I would ignore the transmitter and just try to get the receiver going as the fault, whatever it is, will probably be common to both as above. Coupling your signal generator into it stage by stage (starting with the last IF) should narrow things down.

Best of luck - Joe

Good advice. Also check the LO(s) is/are working properly. It should
be a piece of cake to track down a fault like that, certainly if you
have a schematic.

Hi Group!

My question is about the production of high frequency quartz crystal blanks.
I have lapping and polishing machines with me, i made quite a few number of crystal blanks with frequency upto 20 MHz but above that around 30 to 40 MHz the blanks tend to break a lot, so i would like to get some expert advice regarding which powder to use in lapping, which carriers and other machine parameters. The machine I have is Lapping machine from Hamai.
Hope Someone can come up with some good suggestions.

Thanks in Advance.

Perhaps they are etched. 40 MHz fundamental crystals are readily available
from some suppliers, I've got some.

The 2005 Dodge Caravan we just ordered comes standard
with an AM/FM CD Cassette radio. Yup, it has BOTH a
cd player AND a cassette player!

BTW those cassette adaptors use a tape head run in
reverse for the coupling.

Are you trying to make crystals that have their fundamental resonance
at these high frequencies? One way to get around your problem would be
to use the overtone resonances. That way the crystal won't have to be
as small and fragile.

Just a guess from someone who's interested, but has no direct
experience....

Can you get under the hood and unplug the FM antenna?

Or maybe put a attenuator of some sort in line with it?

Or just cut off the lead in cable?

Obtain a receiver that can handle 530 kHz to 1.7 MHz, install an adequate antenna, scan this range and listen for the code words 'rush,' 'hannity,' and 'savage' among others, and you're listening to them. These stations have followers that blindly obey the dogma broadcast and are a major threat to our democracy and way of life. They will frequently put on communications from their field operatives and those ops sound just like your neighbors in their accent, vocabulary and word usage but their thinking is terrifying. The level of their infiltration is startling, it makes me fear for the future of our country.

==========

I'm afraid you've been caught in the politicians' scare-and war-mongering net. Like Reds under the bed.

The only relatively minor problems we've had in the UK have been with the USA-financed IRA and now that appears to be over and done with.

Sorry I don't have one for sale but I seem to remember that a I-Q vfo
was in the Amateur Radios Handbook several years ago. It may even be
in the newer editions. The projects in the Handbook are virtually kits.
There is usually a source of parts listed and many time you can get
the entire thing in a kit. Some of the parts may not be available
any more, but substitutes shouldn't be that hard to find.

I don't remember the year of the Handbook, but someone else may have
that.

With all due respect, when I went to reply - my computer server said it
didn't recognize that group and the message may not be listed there and
asked to proceed anyway, to which I said yes. So, I am not sure why it
posted there - a computer whiz, I'm not! My intent was not any worse than
others who spot trolls. I've since deleted the person to my computers kill
file.
My apologies to that group. Hopefully they'll see it. This is probably the
one time this message won't be sent to that group - when it is now intended.
However, I'm sure my reply isn't the only one which made it there! He seems
to have caught a few.
But my reply above - to which you replied - was my last to him

4143. beeswax in an oscillator compartment

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-12-15 21:21:28 UTC
From: Larry Gagnon <lagagnon@fakeuniserve.com>
Message-ID: <pan.2004.12.15.21.21.27.858623@fakeuniserve.com>
Source record: 21627

I posted a few days ago about repairing a VHF marine radio. Thankfully I solved my problem, locating three cold solder joints in the VCO, which entailed removing metal shields and all the beeswax that coated all the components. That was character building work!

I gather the beeswax is to ensure rigid components to maintain stability of the oscillator? Any other reasons for it? Is it necessary for me to remelt the old wax and spread it around as before, or can I get away with just reshielding the VCO?

Any suggestions appreciated.

Larry -

Beeswax and encapsulation seemed to be the fad for the Japanese mfg. in the early 1980s. I have heard various reasons, but mobile operation (with potential bouncing and jarring) is often mentioned.
Kenwood amateur gear had some noted PLL problems with their encapsulation materials of that period -- although they were not the only mfg. using this method.

I am curious to know the age of the transceiver and mfg.

Beeswax has been used for securing the windings on toroids.

According to my boss in the late '60s and
early '70s,W.T.G. Glasspool (would you
guess he was British?), beeswax was widely
used in the past to secure coil windings,
seal slugs in the cores of forms and
transformers, etc.. Apparently it doesn't
reduce the "Q" too much, and was readily
available in those days.

I purchased some here in the UK from a local craft shop quite recently. It is an excellent material for holding things together as long as the temperature doesn't get too high and IMHO makes a neater job than hot-melt for holding small items onto a PCB. The trick is to keep an old iron bit especially for the job (and also for starting holes in plastic boxes.) The stuff I got is in the form of small beads and so very easily handled with a pin.

The wax in that VCO, BTW, is anti-microphonic in purpose and definitely should be re-melted. This is particularly important if the loudspeaker is in the same cabinet with the radio.

Cheers - Joe, G3LLV

4152. Suggestion for prescaler up to 3GHz please ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-12-16 12:55:06 UTC
From: sre@lem.com
Message-ID: <264c924d.0412160455.60fa4d63@posting.google.com>
Source record: 21636

Hello,

I'm looking for a prescaler reference with a ratio of 64 and 128, able
to operate up to 3GHz.

I had in mind to use the Motorola MC12079 (64/128, 2.8GHz) but it's
discontinued. The fujitsu MB506 (64/128, 2.4GHz) is difficult to find.

Have you some other part numbers to suggest ?

Many thanks

Stephane, F1TJJ

You might consider one of the PLL chips, such as National's LMX2326, especially if you already will have some digital control lines which you can use to program it. That particular chip can do a 1/32 prescaling, followed by a divide-by-N, but for the LMX2326, N is 3 minimum, so it doesn't do quite what you want. Maybe another such chip would. They are typically quite inexpensive.

Cheers,
Tom

David,

> Does anyone have an I-Q vfo (google it IYDKWTI), kit or built, for sale?
> TIA & 73, Dave, N3HE

Sorry we ran out of them at AmQRP. The sales were brisk while they lasted.
We (George Heron and I) are currently discussing the possibility of another production run.
Let George (AmQRP) know if you are interested.

If anyone is wondering what we are talking about, you can see info and join the discussion in my
YAHOO group - DDS-VFO. I am the moderator and "doorkeeper" just to keep out spam.

Very briefly, it's a 0-30 MHz VFO that I designed. It uses a couple of PIC microcontrollers to run
an AD9854 DDS. This DDS part provides TWO outputs - I (In-phase) and Q (Quadrature - 90 degrees
shifted from the I) which allows many interesting modulation/demodulation possibilities.

I had to Google IYDKWTI and I do know what it is !. ;-)

Beeswax goes back the the 1930s USA designed radios too.
In common radio design use since then.
It is excellent as it has a high melting point (for waxes).
Just put some it back on, it keeps the coils/wires stationary.
You should only need a line on both sides of the coil.

Thanks for your answer Tom

I know this chip, but how do you do to output the pre-scaled signal ?
It would be suitable to use a PLL built-in prescaler if the output was
available on any pin but I don't think this is the case.
My appliaction is a frequency meter

best thing to do is to use your multi-meter

select each wire in turn and look for continuity
these could be the rx wires , next key up and see if the
signal on the meter drops , if so they are the TX/ox -ppt , or one is
and the other will be the gnd , one you know the ground
work around the others , to find the wire that produces
about half scale of the multi-meter , this is most likely
the audio/ or mic wire , now you know 3 wires
its getting less and less for you to have to work out ,
I presume the others must be up & down buttons
and maybe a separate voltage wire .

use the meter or try to look at the radio cct
this should tell you all the info you need to know .

Quite true on old-time radio production, but primarily for the
lower-cost "consumer" type models.

The wax isn't from bees, but rather from other sources and is
usually called "ceresin wax." Pours easily when hot, stays hot
enough for a quick brushing-on. Unfortunately, hot spots in old
tube/valve equipment lets the wax soften and it sometimes dribbles
off and quits holding what it was supposed to hold.

O-T story: Back in 1956 when I was new to WREX-TV and on
midnight maintenance shift, I was supposed to align the air
monitor scope that sampled the transmitter output signal. The
video response was way off judging by the sync signal appearance.
Cause was the peaking coils of the internal tube video amplifier. An
hour spent with a video sweep generator and a hot iron brought the
peaking coils (pie-wound inductors sliding on 1 Watt resistor bodies)
into a good, flat video response. Early day shift complained long and
loud about "the air monitor doesn't work!" It showed the correct
waveform, not the one they were used to! :-) [nobody had been able

to fix it before and all it took was to move the coils slightly to adjust their inductance]

There's nothing special about the wax. It was a convenience to use in production, quick, easy-to-use and cheap. To do a good hold on things like inductors, I would recommend the "spar varnish" kind of varnish (made from pretroleum distilates, not the urethane type). One example of that is McCloskey "Gym Seal" intended for hard-use floor finishing and found in lumber yards and do-it-yourself stores. Varnish needs to cure overnight to be effective, doesn't drop Q any more than the polystyrene "Q Dope" (which will lose its holding power because of moisture breaking the bond to the work), and holds on infinitum (also known as at least 30 years based on my experience).

I'm sure there are some readers who know more about this than I do, but I haven't seen any responses. So I'll post what I know.

A Sinc wave is a non-causal waveform. That means that it starts before the excitation impulse. A perfect sinc wave starts at t = minus infinity, reaches its peak at t = 0, and extends to t = plus infinity. So only a truncated or windowed wave of some sort is possible. But even a truncated one is non-causal. That means you can't make it from any kind of passive components like an LC filter -- you need some sort of delay.

I think the only way you'll be able to generate even a truncated or windowed wave is with a digital filter. I believe an IIR (infinite impulse response) as opposed to FIR (finite impulse response) will be necessary, but I'm not terribly well acquainted with digital filtering techniques so will have to defer to others on that point. The filter would look something like ones used in digital signal processing (DSP), so you might look at references dealing with DSP for some clues.

Get your innovation noticed! Submit it to Wireless Innovation Contest.

If you've created something that's really making a difference, then we want to hear about it. And, more importantly, we want to tell the World about it.

2005 Wireless Innovation Contest takes place in Vancouver, BC Canada.
The 2005 Wireless Innovation Contest is out to prove how wireless is changing the world. It could be a successful product, an enterprise solution that saved your customer thousands of dollars, a government solution that helped save lives or enhanced education or an entertainment solution that has made the world a lot more fun.

Nokia, Telus Mobility and Industry Partners throw Support Behind the Contest this year. A panel of industry leaders will judge each entry and decide on a winner and runner-ups. Winners of WIC 2005 are rewarded with targeted exposure in media and at trade shows, inclusion in a special case study publication and a one-hour mentor session with the panel of judges.

More information is available at www.winbc.org/contest

Remember "fish-paper"? used that in a early 1980 moto radio design.
I know the type of wax you are talking about, harder and a little darker
than beeswax.

Hi Stephane,

You should be able to program the Fo/LD output pin to echo the divider output. See "Table 4" in the data sheet. If you are intent on getting /32, you might check out the LMX2430 series. I think (from a very quick look at the data sheet) that you'll be able to go to lower division ratios with it. It also has a muxed output that can be programmed to echo the divider chain output.

Maybe someone else knows a reason this won't work...I haven't actually done it, but did look into it some time ago and didn't see anything in the data sheet that would make me think it wouldn't work. Seems like these chips are a lot easier to get than simple fast prescalers. Programmable PLL chips from other manufacturers may work well too.
Cheers,
Tom

>a DDS or a similar approach mey be?

An address counter, a lookup table (ROM/RAM) and a DAC should be able to generate any arbitrary waveform.

Since the SINC waveform is symmetric relative to T=0, you just need to store half of the waveform and reverse the up/down address counter at T=0.

Since you are going to need a sample frequency of several hundred MHz to get a clean wave shape, it might be a good idea to use a wide memory system (say 64 bit wide RAM for 8 bit DAC) and run the RAM address counter at fs/8 and either using digital multiplexers to feed a fast DAC at fs or use 8 DACs in parallel at fs/8 and use a fast analog multiplexer.

An other approach is to note that sinc(x) is sin(x)/x or 1/x * sin(x) and generate 1/x and sin(x) separately and use an analog multiplier to multiply them together. You also would have to ensure continuity at x=0. The multiplier accuracy and dynamic range can be a limiting factor in that region. Generating 1/x can be done with lookup tables or with analog multiplier divider chips (which also could generate the sin(x)/x directly) and there are of course multiple ways to generate sin(x).

A DDS chip with AM capability might also be usable by feeding the 1/x as the modulating waveform.

Hello. When I make PCBs for homebrew projects, I often use a Dremel Moto-Tool with a dental bur for cutting the pattern into the copper foil. About ten years ago I bought a bunch of burs from someone at the Dayton Hamvention. Now they're worn out, and I'd like to get some more. Does anyone know where a hobbyist can buy these things? See photo at alt.binaries.pictures.radio .

Do you mean in the frequency domain? that is one pulse 100 ns wide, and
that is it, no filter needed.

Anything else, you need to be clearer on what you want.

"Fish paper" (not made from fish) was common in E-I lamination
transformer construction as a winding insulator. Actually it IS paper
but impregnated with a polymer, good for tight wrapping of wire
layers because it does not have the "give' of many plastic film
wraps. Thin cloth impregnated with phenolic resin was sometimes
used for cheap insulation as a substitute for "fish paper" on non-
transformer structures.

If someone is intent on using any wax, then parafin wax would be
a bit better since its melting temperature is higher than ceresin
waxes. Parafin blocks can be found in larger do-it-yourself stores
such as Lowe's or Home Depot. Harder to work with than the low
temp-melting ceresin wax for potting small things.

Like Joe mentioned, dentists will often be willing to give you some old burs. I don't have many carbide ones, but I do have a whole mess of steel ones that a dentist didn't want to try to sort out after an earthquake many years ago. I might be able to send you a few. Also, I notice as I write this that Google has put some suggestions for dental bur sources in the column adjacent to this... you might try these, or a Google search for dental burs:

www.net32.com, www.dollardiamonds.net, www.hobby-store.us

Also, if you go to your dentist armed with knowledge of how much the burs cost (see net32.com, for example--looks like the best of those three sites for what you want), you might be able to get him/her to sell you some new ones at a reasonable price.

Cheers,
Tom

Hi Joe,
Your call sign indicates that you MIGHT be in the Chicago area.
If you are, you could be in luck. I sold 300 pounds of tungsten carbide
PC board bits to American Science & Surplus a few years back. I
originally purchased them from the Inventory Disposal Store at
Rockwell-Collins, and they were pulled out of service from their board
shop.
The last thing I remember was seeing them at 50 cents each. These are
very good bits.............I only kept 1200 of them for myself.
You can reach them at (773) 763-0313.

Pete

It depends on what kind of accuracy you need.

You could do this analog wise by building a filter that has fast cutoff and linear phase in the passband, and then
applying a very short pulse to it.

A bessel filter is easy to design and has somewhat this characteristic.
Better would be a phase compensated chebeshev design, but I don't think you will find that in a table!

If you look at these filter's responses with an oscilloscope, they will look very Sinc like.

Cliff

The following chip is not recommended for new designs but if its for a home project it should be OK. See the following URL for the data sheet.

http://www.cel.com/pdf/datasheets/upb1506.pdf

There may also be newer versions available if you ask the manufacture.

It's a 'head on' photomultiplier tube.
They were used in flying spot scanners,
and noise generators in radar jammers.

I've found the "asking the dentist for the old worn out tools etc" is a myth. I have asked and the official answer was due to the tools being used in blood, bone and possibly disease they are discarded when worn, not given away. Makes good sense to me! New industrial dental picks and bits are cheap and available all over the place.

There were two versions, a "high" power and a "low" power one. Not racal
as far as I know. I used to use one 25 years ago for 2 metres 10 watts.
It's just a little coupled line with diode probe.

I have no idea why you think these would be amplifiers. It should
be very obvious that they're AC/DC power supplies. Specifically,
standard AC line voltage in, and 28V at 21.5 amps max output.

That would be a wonderful brick for powering military surplus
electronics, as long as all they need is 28V (some required 115VAC at
400Hz as well, multiphase in some cases).

If you're not finding them useful, I would either take them to a
hamfest to sell, or put them up on Ebay.

Keep the peace(es).

Yes, this is what I have seen.

If there were such a risk of disease transmission, then they could
never use the tools on a second patient.

Autoclaving professionally done removes the risk of disease
transmission. It is just a matter of doing it before giving them away.

4197. Tektronix 465 Scope

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-12-21 15:35:06 UTC
From: Dick <dick@langwang.demon.co.uk>
Message-ID: <qEICpBDqKEyBFwrC@langwang.demon.co.uk>
Source record: 21581
Cross-posted to: sci.electronics.design,rec.radio.amateur.homebrew

My Tek 465 scope has developed a minor but annoying fault in its triggering circuitry but before diving into the guts of an old & faithful friend I would appreciate it if anyone who has experienced similar symptoms to those below could give me their thoughts on possible causes & (more importantly) how they fixed their particular version of the problem.

1) My scope just won't trigger in the A Normal mode although a stable trace obtained in A Auto will remain displayed (and stable) in A Normal until I touch either A Trigger slope or polarity controls.

2) I can stabilise a trace using the A Auto mode but only by adjusting the A Trigger Hold-off control rather than the A Trigger slope/polarity I would normally expect.

3) Everything appears to be triggering correctly when I use the B Trigger.

4) All other scope functions appear to be OK.

I've checked these symptoms and they seem to be present what ever type of signal I'm inputting - sine/square, 1kHz - 1MHz, Ch1 or Ch2.

I've got a set of battered circuit diagrams & layout drawings so should at least be able to follow up any ideas you experts might be able to pass my way.

In the mean time many thanks for at least reading this posting and Merry Xmas & Happy New Year to everyone fra' Auld Reekie

It sounds (reads) like a bad connection.

By Ole Occam's razor, and a description of the problem - 'it works
till I touch the knob' - my first guess is a dirty and/or worn
synch selection switch or trigger level pot. The pot wouldn't
happen to have one section for Ch. A and one for B and get
bypassed in Auto, would it?

If it were mine, I would first try a spritz of contact cleaner into
the switch via the front panel slot (IIR465C). All contact
cleaners are the same - mineral oil and alcohol - so the cheapest
Radio Shack stuff works as well as anything. WD40 also works well.

Getting to the switch or pot by disassembly I would save for last.
There is an old adage "Fix anything long enough and you will _really_
break it." And I wish I would remember that adage in time.

Other likely causes are bad connector, crimp or solder joint. After
that electrolytic caps.

4202. 7 BANDER ANNTENA XP707 FROM SOMMER FOR SALE !

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-12-21 17:19:22 UTC
From: Jos&#65533; Lopes <fartolopes@mail.telepac.pt>
Message-ID: <41c85b18$0$26934$a729d347@news.telepac.pt>
Source record: 21586

I am interested in sailing my hf antenna above mentioned that is in very
good conditions.
Reason: need to renew and create a new set up of antennas.
Antenna: Sommer (DJ2UT Beam)
Model: XP 707
Bands: 10, 12, 15, 17, 20, 30 and 40 meters
Balun: The balun furnished with the Sommer antennas is a low-loss
air core type using RG142 (BU) Teflon cable. The balun will handle 2.9 kW
continuous output at 30 MHz with a loss of only 0.05 dB.
This antenna it still on my tower and working very well.
For price please send one email to:
fartolopes@mail.telepac.pt

The transports costs will be at the resposability of the buyer.

==========
On various occsasions I have been told that WD40 is NOT the right cleaning agent for electrical systems involving plastic insulation re wiring, etc. I always use (non chlorinated) contact cleaner as available from Rat Shack and similar stores.
Here in the UK I use contact cleaner supplied by Maplin.

Have you cleaned the controls and switches? Electromechanical parts are
the weakest link.

Ugh. and Ugh again.

I'd raise three cautions about this advice:

[1] My recollection is that Tek specifically warns against using
most contact cleaners on, or around, certain of the internal
controls (e.g. the attenuator switches). These switches are
apparently quite sensitive to contamination, as they deal with
high-impedance signals. Spraying an oil-and-alcohol contact
cleaner anywhere in their area might very well contaminate them.

IIRC, Tek's recommendation is to use pure isopropyl alcohol, and
a small clean brush, for cleaning contacts.

[2] Not all contact cleaners are the same. Many used for sensitive
equipment are "zero-residue" types - they have a cleaning solvent
and propellant, but do not contain any sort of lubricant, and are
intended to leave nothing behind on the contacts. Even among the
contact treatments which do contain a lubricant of some sort, there
is wide variation in the type of solvent used (some use alcohol,
some use a hydrocarbon or chlorinated/fluorinated hydrocarbon)
and the lubricant used (some use mineral oil, some a polyphenyl
ether, others something else entirely). It pays to use the right
combination for the job.

[3] I would not use WD-40 as a contact cleaner, on anything less robust
than an electric motor. It's not formulated for that purpose
(in fact, it's not really formulated as a long-term lubricant!)
and it is notorious for getting gummy and attracting dust over
the long run.

At the moment I'm having a fight with my Dynatek. So I looked up this
section in the schematics. Triggering looks simple. The trigger signal is
enabled/disabled by the outputs of a flipflop (LS74 here) which is
set/cleared by the channel selector switch. Here the switch is floating to
select Channel 2. So a bad contact will select channel 2. It looks almost
too simple, but an attack with contact cleaner may cure your old friend.

NONONONONONONO!!!! DEFINITELY NOT!!!!!

All contact cleaners ARE NOT the same! Never have been, never will
be, and the proper ones for degreasing electronic equipment do NOT
contain any mineral oil!

I speak from knowledge gained over 25+ years of pro experience in
the fields of radio, electronics, and computers. NEVER, under ANY
conditions, use WD40 inside a Tektronix 'scope or any other electronic
device! It leaves an oily residue which will actually ATTRACT dirt and
gunge, and make the problem worse.

If you value your test equipment, don't cut corners on the stuff
you use to maintain it. Check the Tektronix service manual for the
recommended cleaner formulation, and get it from a quality electronics
supply place (Radio Shack does NOT come under that category as far as
I'm concerned).

I can tell you from personal experience that CRC 'CO Contact
Cleaner' works very well, and it is plastic-safe so you won't damage the
innards of the vertical attenuator assemblies.

It may cost a little more up front, or be a little harder to find,
but you won't be risking the long-term life of said equipment.

Happy hunting.

A number of the switches on the 465 use PC board pads as contacts. They have heavy gold plating, but eventually the gold wears off. When that happens, the switch is dead and as far as I know can't be repaired. You might be able to squeeze a little more life out of it by cleaning, but in any case I'd be very careful not to use a cleaner with any abrasive qualities. If cleaning doesn't cure the problem, worn pads might be the cause.

But by all means check with the 'scope newsgroup. I'm sure you'll find folks who have had a lot of experience with the 465, and some might even know of some kind of fix or replacement for worn switch contact pads.

it was used in a construction (QST) 20 years ago, and the writer
mentioned it was somewhat dated then, not to easy to get gain. the
only reason to use it was the price, so I wonder if it is difficult to
find a better device now?

My first 6m amplifier from '85 used BLY94 because it was free, but it
cannot give more than 60-70W

On TEK LF or HF cam style contact switches,do NOT use mineral oil-based
cleaner/lubes.Take some 99% isopropyl alco,wet a narrow paper strip,and
slide under the closed contact,and move back and forth.These cam-style
switches have VERY low wiping force,and any oil,grease,or film will cause
intermittents or opens.

I suspect a calibration may improve his triggering,too.

You know, it's funny how often these debates flare up over a subject as mundane as contact cleaner. "My tuner cleaner is better than your tuner cleaner. Your tuner cleaner should be used only in Ukrainian opposition candidates' minestrone. My tuner cleaner costs more than HP printer ink. If you spray your tuner cleaner on a Tektronix 465, it will trigger a resonance cascade and gate in alien overlords from the planet Xen." Yadda, yadda, yadda.

Despite all the gurus out there forking the evil eye at WD-40, I sure seem to own a lot of stuff that still works fine after being sprayed with WD-40 over the years (decades, in some cases). Yeah, I know. "Data: n, plural of 'anecdote'."

Some of these gurus are admittedly respected veterans of companies such as Tektronix, with whom mere mortals are loath to argue. All I can say is, those switches must not have been of the greatest quality in the first place, or the gurus wouldn't have to spend so much of their time on Usenet warning people against hosing them down with WD-40.

Just sayin', is all. No disrespect intended. :)

LOL. Well, some switches on oscilloscopes are very fragile with many,
many contacts, and rather low contact pressure. Sometimes hermetically
sealed too, so you can even use a spray can of Spam or shaving foam and
it won't hurt a bit ;)

The discussion about contact cleaner isn't altogether mundane.

I worked at Tek for many years, although I'm certainly not a guru when it comes to oscilloscope maintenance. But I do recall one experience with cleaning solvents and board-mounted switches.

Before introducing a new instrument, we went through a lengthy process of building and testing prototypes, which I described some time ago in this newsgroup. In one group, it was our practice to borrow some assemblers from production to build the prototypes. One afternoon I was looking at some units they had built, after they had left for the day, and saw that the plastic of some switch bodies was very badly crazed -- they were covered with tiny cracks. Some experiments with bottles of solvent we found in some of the assemblers' work areas pinned it down to one particular liquid. The problem was one of the ingredients, which was a relatively common solvent of the time. Unfortunately, I don't recall which one -- it was something pretty mild as solvents go, like toluene or Freon, not a relatively strong solvent like acetone, which we all knew better than to use. We found out that the solvent had been banned from production, but the assemblers kept a supply out of sight because it was really good at removing flux.

The lesson is that even some normally pretty innocent solvents can destroy some plastics. Other components can also be ruined by various solvents, so that's another reason to use some caution. As just one example, it was found that Freon and its relatives would migrate up the leads and into even pretty well sealed radial leaded aluminum electrolytic capacitors, corroding the insides and causing premature failure. This was solved by improving the end seals, but only after a lot of the older type reached the field, some on boards having been washed with Freon. Of course, Freon is no longer used, but there are a host of other potential problems. It's ultimately up to you to decide whether you want to experiment with your scope.

As for WD-40, I love the stuff and use it on all kinds of switches and electrical components. But I mentioned a short while ago that the cam switches in the 465 and some other scopes use PC board pads for contacts, and when the pad's gold plating is gone, the switch -- and the scope -- is dead. So it doesn't seem like a good thing to me to use a cleaner on those that'll leave a film which can collect dust or anything abrasive.

I don't agree that a switch's ability to withstand WD-40 or any other particular chemical is an indicator of its quality. But we all have our own criteria we use to judge.

Roy Lewallen, W7EL

Making your own rotator system is probably more trouble than it is worth.
For smaller antennas you could always use an "Armstrong Rotator" -- in fact,
the more you use one of these simple rotators, the larger the antenna array
you will be able to move.

I went this route a few years back, built a push-pull MRF476(?) with bias for SSB, and after messing around with it for almost a year rewinding transformers and playing with bias and tank caps trying to get more than 100 watts or so in RF instead of heat I wish I'd just bought a Mirage or TE and started my current project sooner, building a 6m/2m amp with a GS35B,

http://www.nd2x.net/yu1aw-6n2.html
on
http://www.nd2x.net/base-1.html

If you really want to build in addition to articles there's
http://www.communication-concepts.com/
with stuff like
http://www.communication-concepts.com/ar313.htm

My advice:
I think 100w+/- solid state amps are cheap enough to buy used and not build. If you want to build don't waste your time below +55 dBm, go for the legal limit.

==========
First a few questions :
1) What type of rotating antenna do you intend using , a small Yagi ,a large Yagi , a small or big Quad antenna ?
2) Do you suffer ,from time to time , from high winds in your area ?

Especially heavy rotating antennas with a relatively high wind loading need a powerful motor/gearbox + a BRAKE !
The latter is an absolute necessity otherwise the internal gear train will be wasted in a short time.
Another requirement for the rotor is to be weather proof.
If the whole mast , either fitted against a building or other elevated structure (steel tower) ,is rotating from top to bottom (inside bearings) the electric rotator can be fitted at ground floor level . This allows some freedom in selecting electric motor + gear box and brake . In this situation you might not need an electric drive at all since the rotation could possibly be established by purely mechanical means (pulleys + belt/cable/rope) with a ditto clamp preventing rotation when stationary.

However with the rotator in an elevated position (near the antenna) a homebrew unit is probably 'very difficult' .
Perhaps others on this NG would care to comment.

when I first started as a ham (in the early 1960's) people used "prop-pitch"
motors for their antennae -- I don't know if Fair Radio has them anymore --
they were a regular item at the Dayton Hamfest way back then.

I just sold a CDR rotor (with controller) on EBay a few months ago.

That was also my impression. But I have used it on plastics and
have not found any problems after 20 years. Famous last words,
I know. I have used it as a contact cleaner with great success.

It is possible to re-plate the gold. But imagining the circuit board
it may be impossible to mask the components. Aw, what the heck - gold
plate the whole thing and screw it to your Hinkley yacht.

And at the other extreme, when I was first a ham in the mid 90's, I used a
tv rotator on a push up pole rotating a 3 element 2m yagi and a 40 m dipole
made with 2 40 m mobile whips. It all depends on the antenna array you
intend to move and what the winds are going to be like.
thanks, John.

I recently gave away a 465 that was giving me fits. I don't know what happened to it, but it had squirrelly problems all over. It was shipped to Tek for repair in the early 1990's and Tek said it was unrepairable. Of course I knew better.......

It was used extensively in field service, and was probably vibrated to death, but it had the damndest problems I ever saw. The ones that really killed me (other than the vertical attenuator switches) were an oscillation in the Ch 1 vertical, inability to get a smooth leading edge on a fast rise (fall was OK) and an intermittently failing intensified sweep. I spent about 100 hours on that thing and never did get it to work right. I don't know if that had multi-layer boards or not, but it acted like some inaccessible connections were intermittent. I checked and changed component after component, and there would always be one more trouble. That was my weekend for a few months; I would start and go througn the WHOLE calibration procedure (including the stuff that everybody skips, like swinging the line to check the power supply at high and low line conditions) to see how far I could get this time. Undoubtedly I would stop at some point because the adjustment didn't have enough range or some such. I'd fix that and next week a different set of stuff wouldn't work. The problems were never expensive stuff, just resistors and capacitors.

That was the ONLY Tek scope that ever stumped me. I even managed to keep a 647 running, and those NEVER worked.

Yes indeed. The perversity of the inanimate.

So I gave away the 465 and bought a TDS2012. Took a little getting used to, but I've never looked back. Still have the old reliable 547 and a whole slew of plug-ins in the corner, but they are going to need a new home before too long.

Well, it did come with a three year warranty, and it does work well right
now, which is more than the 465 did. But I hear you. Time will tell.

Trying to support a TEK product without the Tek selected transistors and
other specialized components is extremely difficult.
One of the first things I did when getting a unit that someone else had
tried to repair was to find and remove all the non-Tek xstrs,and replace
with the proper TEK parts.They were often causes of oscillations and bad HF
responses.Some scopes may have had ferrite beads used in some places lost
or not installed with the new transistors.One other common problem was a

black silver oxide growing on the tiny HF trimmer caps,especially on the bottom of them,acting as an insulator and making the cap open and ineffective.

IMO,the HF cam contacts used in the attenuators should be failing and no longer repairable due to the plastic part that holds the gold contact to the spring metal degrading and coming apart,or loss of spring tension. That's a problem with using plastic parts,they outgass and eventually degrade and lose strength.Some of the atten intermittents can be due to the outgassing making a film on the contacts and pads.

TEK has a Long Term Product Support(LTPS) policy,where the item will be
serviceable by TEK X number of years after it's last sold in their catalog.
They have a list of whats supported and for how long on their website,IIRC.
"X" used to be 9 years,then got cut to 6,then some items are only ONE year.
That's why you have to check the list.
Also,repair prices climb in the last couple of years of "support",to
encourage you to buy a new unit.

AFTER the LTPS period is over,the item is no longer supported at all.
No exchange modules,and no parts support unless the part is used in a
current product.

Yes, this unit could indeed have had some non-Tek semiconductors in it. I got the HF ocsillation to stop by putting a few gimmick capacitors, less that 1 pF, at the output of the Ch 1 vertical amp. Didn't affect the frequency response any, but the vertical output amp had a few extra time constants visible on a leading edge that none of the adjustments would control.

It was a real learning experience, but the patient died. One thing I DID learn was that gold-plated sockets don't mean a thing if they mate with tinned leads. When I first got that scope almost nothing worked, and major recovery was effected by removing and replacing all the socketed connectiions, which in that scope included virtually all of the semiconductors. I also suspected that that scope was not a "complete" instrument; seems to me that the versions and serial numbers didn't really agree, as if someone tried to make one good scope out of parts from other ones that were of varying vintages.

Anyway, I decided that I am out of the scope-fixing business. It's kind of like changing the engine in a car, the first couple dozen are fun, and after that its just plain work.

May well have been toluene. It was often used as a cleaner in all sorts of
areas, some as pedestrian as the T/R/S plugs on old lamp-signalling telephone
switchboards. Unfortunately proved to be a carcinogen and was banned, but it
WAS used to clean a myriad of hardware in a myriad of situations.

Banned? Perhaps from use as a general solvent in assembly areas, but if you walk into most hardware stores (such as Ace), you can buy it in gallons in their paint sections... Pretty cheap too!

It's at least a bit amazing that one industry may ban an item, yet another still provides it...
It seems that you can't purchase lacquer paint for an automobile anywhere at this point, yet can still buy gallons of lacquer thinner (and lacquer based paints for wood) at the local hardware store... sigh...

True enough in the case of the 465. That model in particular seems to
have been very robust. You don't see many owners asking about how to
clean 465 switches.

485 switches, though, are another thing entirely. It's very rare to see
a 485 whose vertical attenuator switches aren't noisy. Perhaps gold-pad
abrasion has caught up to the instruments over time; however, I'm
personally aware of at least two anecdotal cases of noisy 485 switches
being fixed (at least for the time being) with contact cleaner.

It's possible there's more than one cause of switch degradation at work
in the 485 and other notorious "problem children." Either way, though,
the original designers were clearly not omniscient in all cases, or the
problems with certain models wouldn't be as widespread as they are. I
wish there were a sure-fire way to fix the 485's front-end switches; it
was my favorite Tek scope of the bunch otherwise.

I read in sci.electronics.design that budgie <me@privacy.net> wrote (in <9ueks0tkk5131gj11cf1mogcea1krvj32f@4ax.com>) about 'Tektronix 465 Scope', on Thu, 23 Dec 2004:

>May well have been toluene. It was often used as a cleaner in all sorts
>of areas, some as pedestrian as the T/R/S plugs on old lamp-signalling
>telephone switchboards. Unfortunately proved to be a carcinogen and was
>banned, but it WAS used to clean a myriad of hardware in a myriad of
>situations.

Toluene is one of the aromatics that is NOT carcinogenic. From the ATSDR web site:

QUOTE
Studies in workers and animals exposed to toluene generally indicate that toluene does not cause cancer. The International Agency for Research on Cancer (IARC) and the Department of Health and Human Services (DHHS) have not classified toluene for carcinogenic effects. The EPA has determined that toluene is not classifiable as to its human carcinogenicity.
ENDQUOTE

Toluene is available in small quantities as a solvent for contact adhesive. It DOES attack some plastics, and those it attacks slowly can exhibit surface dulling and crazing.

It might have been carbon tet (tetracloride or however it is spelled). I
think it was taken off the market because of either liver or kidney failure
if the user had been drinking .

When carbon tet was removed from telephone offices there was a story
about a technician spilling some
on a operator. The operator lost here hair and finger nails. Don't know
if that is true but we had to
remove all carbon tet from the cleaning supplies.

Standard GX-3000 VHF APRS Radios. [with DTMF]
I have a quantity of Commercial Standard GX-3000 VHF Mobile Radios (136-150Mhz) 25-30 Watts O/P These radios will work excellent as an APRS Mobile OR Base Radio Station. Units are much cheaper to use for dedicated APRS use rather than spending Large Dollars for a VHF Amateur XCVR and dedicate it to APRS use. Programmed & Tested Operational on 144.390 Mhz. You will have to make up the Interface Cable. These radios are capable of 64 Channels, Carrier Squelch Only and I can program them for other 2 Meter Frequencies for a charge. Please ask should you have any questions.
Cost: $45 USD plus shipping

Both 465 and 485 use the same HF cam switch contacts.

TEK used to have a repair kit that included both contacts,drill bits to
remove the securing rivets,and tiny nuts and bolts to secure the new
contacts.

They also had a repair kit for the LF contacts used in the timing
switch,with an alignment guide to get them straight.

Both are no longer available.

Yeah, that's the stoopid guv'mint for ya! If they was just as smart as we was, they wouldn't ban all this neat stuff.

According to a hazmat data sheet I have, carbon tet (which can be absorbed by breathing, skin contact, or ingestion) causes damage to the liver, kidneys, heart, adrenal glands, and nervous system, and is particularly dangerous to people who have recently consumed alcohol, are exceedingly fleshy or are undernourished, or have other problems like hypertension. You can smell it at a concentration of 70 ppm; toxicity is known at concentrations of 5 ppm.

I used the stuff quite a bit when I was a kid, and I'm just fine (I think) so that's obvious proof that it's all a bunch of hogwash and a government conspiracy.

Personally, I favor allowing anyone to buy and sell any kind of hazardous chemical or object. By banning them, we've interfered with natural selection, which seems to be resulting in a less and less intelligent population. A sort of "unintelligent design" as it were.

Carbon tet was used in the dry cleaning industry in the early 20th century. People worked over open vats, breathing the fumes all day long, and it took about 20 years of exposure for harm to be done. It is an excellent solvent for general purpose cleaning. I'm sorry it was banned.

I used in the TV service business back in the olden days and I'm perfectly n..n..n..normal, just like Roy.

On the other hand, some people would say this explains a lot. :-)

They would actually make quite good switching mixers. I've seen a design
somewhere but can't remember where. It was a long time ago.

Leon

Hm, the Center for Disease Control must have accumulated faulty data over all those years (See http://www.atsdr.cdc.gov/toxprofiles/tp30-c3.pdf). Of course, it's a government agency, so they probably just made all that up as part of a liberal-pinko plot to control our minds and our precious bodily fluids. I'm sure we can get much more reliable information from those folks on AM talk radio, who don't have any agenda but just want to get the truth out. Those of us who breathed carbon tet in our formative years can see through all those guvmint plots!

High Frequency cam switches,the ones used in the attenuators.Different from
the LF contacts used in the timing switch area.The HF contacts have a
plastic piece insulating the actual goldplated contact from the spring arm.
LF contacts are one piece spring phosphor-bronze.

WARNING
Not all cans obey the same "color code"
However for AM cans it seems that
RED slugs are oscillator coils,
1st IF cans are often YELLOW, 2nd IF
cans are WHITE, 3rd IF cans are BLACK or BLUE
I don't know about the FM ones.

roast than to buy stew meat).

1 stillbirth, de-boned and cubed
&#65533; cup vegetable oil
2 large onions
bell pepper
celery
garlic
&#65533; cup red wine
3 Irish potatoes
2 large carrots

This is a simple classic stew that makes natural gravy,
thus it does not have to be thickened.
Brown the meat quickly in very hot oil, remove and set aside.
Brown the onions, celery, pepper and garlic.
De-glaze with wine, return meat to the pan and season well.
Stew on low fire adding small amounts of water and
seasoning as necessary.
After at least half an hour, add the carrots and potatoes,
and simmer till root vegetables break with a fork.
Cook a fresh pot of long grained white rice.

Pre-mie Pot Pie

When working with prematurely delivered newborns (or chicken) use sherry;
red wine with beef (buy steak or roast, do not pre-boil).

Pie crust (see index)
Whole fresh pre-mie; eviscerated, head, hands and feet removed
Onions, bell pepper, celery
&#65533; cup wine
Root vegetables of choice (turnips, carrots, potatoes, etc) cubed

Make a crust from scratch - or go shamefully to the frozen food section
of your favorite grocery and select 2 high quality pie crusts (you
will need one for the top also).
Boil the prepared delicacy until the meat starts to come off the bones.
Remove, de-bone and cube; continue to reduce the broth.
Brown the onions, p

of protein.

2 human baby rib racks
3 cups barbecue sauce or honey glaze (see index)
Salt
black pepper
white pepper
paprika

Remove the silverskin by loosening from the edges,
then stripping off.
Season generously, rubbing the mixture into the baby?s flesh.
Place 1 quart water in a baking pan, the meat on a wire rack.
Bake uncovered in 250° oven for 1° hours.
When browned, remove and glaze,
return to oven and bake 20 minutes more to form a glaze.
Cut ribs into individual pieces and serve with extra sauce.

Fresh Sausage

If it becomes necessary to hide the fact that you are eating
human babies, this is the perfect solution.
But if you are still paranoid, you can substitute pork butt.

5 lb. lean chuck roast
3 lb. prime baby butt
2 tablespoons each:
salt
black, white and cayenne peppers
celery salt
garlic powder
parsley flakes
brown sugar
1 teaspoon sage
2 onions
6 cloves garlic
bunch green onions, chopped

Cut the children?s butts and the beef roast into pieces
that wi

beef roast if the haunch
it is in any way diseased. But sometimes surgeons make mistakes,
and if a healthy young limb is at hand, then don?t hesitate to cook
it to perfection!

1 high quality limb, rack, or roast
Potatoes, carrot
Oil
celery
onions
green onions
parsley
garlic
salt, pepper, etc
2 cups beef stock

Marinate meat (optional, not necessary with better cuts).
Season liberally and lace with garlic cloves by making incisions,
and placing whole cloves deep into the meat.
Grease a baking pan, and fill with a thick bed of onions,
celery, green onions, and parsley.
Place roast on top with fat side up.
Place uncovered in 500° oven for 20 minutes, reduce oven to 325°.
Bake till medium rare (150°) and let roast rest.
Pour stock over onions and drippings, carve the meat and
place the slices in the au jus.

Bisque à l?Enfant

Honor the memory of Grandma with this dish by utilizing her good
silver soup tureen and her great grandchildren (crawfish, crab or
lobster will work just as well, however this dish is classically
made with crawfish).

Stuffed infant heads, stuffed crawfish heads, stuffed crab or lobster shells;
make patties if shell or head is not available
(such as with packaged crawfish, crab, or headless baby).
Flour
oil
onions
bell peppers
garlic salt, pepper, etc.
3 cups chicken stock
2 sticks butter
3 tablespoons oil

First stuff the heads, or make

stuffing (see index)
½ cup melted butter

Remove the giblets from the infant and set aside.
Stuff the cavity where the child?s genitals and anus were located
using ½ cup per pound of meat.
Tie the arms flat to the body, then pull the skin flaps up to close the cavity.
Now tie the thighs up tight to hold it all together.
Place breast side up in a large metal roasting pan.
Bake in 325½ oven covered for 2 hours.
Remove cover, stick a cooking thermometer deep into one of the
baby?s buttocks and cook uncovered till thermometer reads 190½,
about another hour.

Pro-Choice Po-Boy

Soft-shelled crabs serve just as well in this classic southern delicacy.
The sandwich originated in New Orleans, where an abundance of abortion clinics
thrive and hot French bread is always available.

2 cleaned fetuses, head on
2 eggs
1 tablespoon yellow mustard
1 cup seasoned flour
oil enough for deep frying
1 loaf French bread
Lettuce
tomatoes
mayonnaise, etc.

Marinate the fetuses in the egg-mustard mixture.
Dredge thoroughly in flour.
Fry at 375½ until crispy golden brown.
Remove and place on paper towels.

Holiday Youngster

One can easily adapt this recipe to ham, though as presented,
it violates no religious taboos against swine.

1 large toddler or small child, cleaned and de-headed
Kentucky Bourbon Sauce (see index)
1 large can pineapple slices
Whole cloves

Place him (or ham) or her in a large glass baking dish, buttocks up.
Tie with butcher string around and across so that he looks like
he?s crawling.
Glaze, then arrange pineapples and secure with cloves.
Bake uncovered in 350° oven till thermometer reaches 160°.

Cajun Babies

Just like crabs or crawfish, babies are boiled

off.
Season generously, rubbing the mixture into the baby?s flesh.
Place 1 quart water in a baking pan, the meat on a wire rack.
Bake uncovered in 250&#65533; oven for 1&#65533; hours.
When browned, remove and glaze,
return to oven and bake 20 minutes more to form a glaze.
Cut ribs into individual pieces and serve with extra sauce.

```
Fresh Sausage

If it becomes necessary to hide the fact that you are eating
human babies, this is the perfect solution.
But if you are still paranoid, you can substitute pork butt.

5 lb. lean chuck roast
3 lb. prime baby butt
2 tablespoons each:
salt
black, white and cayenne peppers
celery salt
garlic powder
parsley flakes
brown sugar
1 teaspoon sage
2 onions
6 cloves garlic
bunch green onions, chopped

Cut the children?s butts and the beef roast into pieces
that will fit in the grinder.
Run the meat through using a 3/16 grinding plate.
Add garlic, onions and seasoning then mix well.
Add just enough water for a smooth consistency, then mix again.
Form the sausage mixture into patties or stuff into natural casings.

Stillborn Stew

By definition, this meat cannot be had altogether fresh,
but have the lifeless unfortunate available immediately after delivery,
or use high quality beef or pork roasts (it is cheaper and better to
cut up a whole roast than to buy stew meat).
```

1 stillbirth, de-boned and cubed
&#65533; cup vegetable oil
2 large onions

rare, yearling, or the
morticians occasional horror: a small miracle stopped short by a
drunk driver, or the innocent victim of a drive-by shooting...

2 cups finely chopped very young human flesh
1 cup shredded cabbage
1 cup bean sprouts
5 sprigs green onion, finely chopped
5 cloves minced garlic
4-6 ounces bamboo shoots
Sherry
chicken broth
oil for deep frying (1 gallon)
Salt
pepper
soy & teriyaki
minced ginger, etc.
1 tablespoon cornstarch dissolved in a little cold water
1 egg beaten

Make the stuffing:
Marinate the flesh in a mixture of soy and teriyaki sauces
then stir fry in hot oil for till brown - about 1 minute, remove.
Stir-fry the vegetables.
Put the meat back into the wok and adjust the seasoning.
De-glaze with sherry, cooking off the alcohol.
Add broth (optional) cook a few more minutes.
Add the cornstarch, cook a few minutes till thick,
then place the stuffing into a colander and cool;
2 hours
Wrap the rolls:
Place 3 tablespoons of stuffing in the wrap, roll tightly -
corner nearest you first, fold 2 side corners in,
wrap till remaining corner is left.
Brush with egg, seal, and allow to sit on the seal for
a few minutes.
Fry the rolls:
325&#65533; if using egg roll wraps, 350&#65533; for spring roll wraps.
Deep fry in peanut oil till crispy golden brown, drain on paper towels.

Lemon Neonate

Turkey serves just as well, and in fact even looks a bit like a
well-dressed baby. By the time you turn the child?s breast into

cutlets, it will be indistinguishable. The taste of young human, although similar to turkey (and chicken) often can be wildly different depending upon what he or she has consumed during its 10 to 14 months of life...

4 well chosen cutlets (from the breasts of 2 healthy neonates)
2 large lemons (fresh lemons always, if possible)
Olive oil
Green onions
Salt
pepper
cornstarch
neonate stock (chicken, or turk

vegetables, and
fruit such as pineapples or cherries on the skewers.
Don?t be afraid to use a variety of meats.
Grill to medium rare,
serve with garlic cous-cous and saut&#65533;ed asparagus.
Coffee and sherbet for desert then walnuts, cheese, and port.
Cigars for the gentlemen (and ladies if they so desire)!

Crock-Pot Crack Baby

When the quivering, hopelessly addicted crack baby succumbs to death,
get him immediately butchered and into the crock-pot, so that any
remaining toxins will not be fatal. But don?t cook it too long,
because like Blowfish, there is a perfect medium between the poisonous
and the stimulating. Though it may not have the same effect on your
guests, a whole chicken cooked in this fashion is also mighty tasty.

1 newborn - cocaine addicted, freshly expired, cleaned and butchered
Carrots
onions
leeks
celery
bell pepper
potatoes
Salt
pepper
garlic, etc
4 cups water

Cut the meat into natural pieces and brown very well in olive oil,
remove, then brown half of the onions, the bell pepper, and celery.
When brown, mix everything into the crock-pot, and in 6 to 8 hours you
have turned a hopeless tragedy into a heartwarming meal!

George?s Bloody Mary

Don?t shy away from this one, it is simply a cocktail variation of
good old Blood Stew. When a pig is killed, its throat is slit and
those present quaff a cup of hot blood to soften the wintry air.
From the dawn of man to this day, humans have always drunk blood!
American deer hunters are a prime example.

1 pint blood
Stolichnaya vodka
ice

tomato juice
lemon
lime
hot sauce
Worcestershire sauce
pickled green bean
celery
green olives
celery salt

Draw a pint of blood from a very young virgin,
female if possible, and chill.
In a tall glass pour 1 or 2 ounces of vodka,
then add 6 ounces each of blood and V8 or tomato juice.
Add ice and other ingredients, making it somewhat spicy.

Opiated Bloody Mary

When alcohol is not e

fetuses, head on
2 eggs
1 tablespoon yellow mustard
1 cup seasoned flour
oil enough for deep frying
1 loaf French bread
Lettuce
tomatoes
mayonnaise, etc.

Marinate the fetuses in the egg-mustard mixture.
Dredge thoroughly in flour.
Fry at 375° until crispy golden brown.
Remove and place on paper towels.

Holiday Youngster

One can easily adapt this recipe to ham, though as presented,
it violates no religious taboos against swine.

1 large toddler or small child, cleaned and de-headed
Kentucky Bourbon Sauce (see index)
1 large can pineapple slices
Whole cloves

Place him (or ham) or her in a large glass baking dish, buttocks up.
Tie with butcher string around and across so that he looks like
he?s crawling.
Glaze, then arrange pineapples and secure with cloves.
Bake uncovered in 350° oven till thermometer reaches 160°.

Cajun Babies

Just like crabs or crawfish, babies are boiled alive!
You don?t need silverware, the hot spicy meat comes off in your hands.

6 live babies
1 lb. smoked sausage
4 lemons
whole garlic
2 lb. new potatoes
4 ears corn
1 box salt
crab boil

Bring 3 gallons of water to a boil.
Add sausage, salt, crab boil, lemons and garlic.
Drop potatoes in, boil for 4 minutes.
Corn is added next, boil an additional 11 minutes.
Put the live babies into the boiling water and cover.
Boil till meat comes off easily with a fork.

Oven-Baked Baby-Back Ribs

Beef ribs or pork ribs can be used in this recipe,
and that is exactly what your dinner guests will assume!
An excellent way to expose the uninitiated to this highly misunderstood
yet succulent source of protein.

2 human baby rib racks
3 cups barbe

Oven-Baked Baby-Back Ribs

Beef ribs or pork ribs can be used in this recipe,
and that is exactly what your dinner guests will assume!
An excellent way to expose the uninitiated to this highly misunderstood
yet succulent source of protein.

2 human baby rib racks
3 cups barbecue sauce or honey glaze (see index)
Salt
black pepper
white pepper
paprika

Remove the silverskin by loosening from the edges,
then stripping off.
Season generously, rubbing the mixture into the baby?s flesh.
Place 1 quart water in a baking pan, the meat on a wire rack.
Bake uncovered in 250&#65533; oven for 1&#65533; hours.
When browned, remove and glaze,
return to oven and bake 20 minutes more to form a glaze.
Cut ribs into individual pieces and serve with extra sauce.

Fresh Sausage

If it becomes necessary to hide the fact that you are eating
human babies, this is the perfect solution.
But if you are still paranoid, you can substitute pork butt.

5 lb. lean chuck roast
3 lb. prime baby butt

2 tablespoons each:
salt
black, white and cayenne peppers
celery salt
garlic powder
parsley flakes
brown sugar
1 teaspoon sage
2 onions
6 cloves garl

stock,
so that it remains boiling the whole time.
Cover the pot and simmer till vegetables are tender
(2 hours approximately).
Continue seasoning to taste.
Before serving, add butter and pasta,
serve piping with hot bread and butter.

Offspring Rolls

Similar to Vietnamese style fried rolls, they have lots of meat
(of course this can consist of chicken, beef, pork, or shrimp).
Who can resist this classic appetizer; or light lunch served with
a fresh salad? Versatility is probably this recipe?s greatest virtue,
as one can use the best part of a prime, rare, yearling, or the
morticians occasional horror: a small miracle stopped short by a
drunk driver, or the innocent victim of a drive-by shooting...

2 cups finely chopped very young human flesh
1 cup shredded cabbage
1 cup bean sprouts
5 sprigs green onion, finely chopped
5 cloves minced garlic
4-6 ounces bamboo shoots
Sherry
chicken broth
oil for deep frying (1 gallon)
Salt
pepper
soy & teriyaki
minced ginger, etc.
1 tablespoon cornstarch dissolved in a little cold water
1 egg beaten

Make the stuffing:
Marinate the flesh in

Stillborn Stew

By definition, this meat cannot be had altogether fresh,
but have the lifeless unfortunate available immediately after delivery,
or use high quality beef or pork roasts (it is cheaper and better to
cut up a whole roast than to buy stew meat).

1 stillbirth, de-boned and cubed
½ cup vegetable oil
2 large onions
bell pepper
celery
garlic
½ cup red wine
3 Irish potatoes
2 large carrots

This is a simple classic stew that makes natural gravy,
thus it does not have to be thickened.
Brown the meat quickly in very hot oil, remove and set aside.
Brown the onions, celery, pepper and garlic.
De-glaze with wine, return meat to the pan and season well.
Stew on low fire adding small amounts of water and
seasoning as necessary.
After at least half an hour, add the carrots and potatoes,
and simmer till root vegetables break with a fork.
Cook a fresh pot of long grained white rice.

Pre-mie Pot Pie

When working with prematurely delivered newborns (or chicken) use sherry;
red wine with beef (buy steak or roast, do not pre-boil).

Pie crust (see index)
Whole fresh pre-mie; eviscerated, head, hands and feet removed
Onions, bell pepper, celery
½ cup wine
Root vegetables of choice (turnips, carrots, potatoes, etc) cubed

Make a crust from scratch - or go shamefully to the frozen food section
of your favorite grocery and select 2 high quality pie crusts (you
will need one for the top also).
Boil the prepared delicacy until the meat starts to co

Bake at 325° for 30 - 45 minutes.
Serve with hot dinner rolls, fruit salad and sparkling water.

B°b° Buffet 1

Show off with whole roasted children replete with apples in mouths -
and babies? heads stuffed with wild rice. Or keep it simple with a
hearty main course such as stew, lasagna, or meat loaf.

Some suggestions

Pre-mie pot pies, beef stew, leg of lamb, stuffed chicken, roast pork spiral ham,
Cranberry pineapple salad, sweet potatoes in butter, vegetable platter, tossed salad with
tomato and avocado, parsley new potatoes, spinich cucumber salad, fruit salad
Bran muffins, dinner rolls, soft breadsticks, rice pilaf, croissants
Apple cake with rum sauce, frosted banana nut bread sherbet, home made brownies
Iced tea, water, beer, bloody marys, lemonade, coffee

The guests select food, beverages, silverware... everything from the buffet table.
They move to wherever they are comfortable, and sit with whoever they choose.
Provide trays so your guests will not spill everything all over your house from
carrying too much, nor will they have to make 10 trips back and fourth from the
service stations.

Roast Leg of Amputee

By all means, substitute lamb or a good beef roast if the haunch
it is in any way diseased. But sometimes surgeons make mistakes,
and if a healthy young limb is at hand, then don?t hesitate to cook
it to perfection!

1 high quality limb, rack, or roast
Potatoes, carrot
Oil
celery
onions
green onions
parsley
garlic
salt, pepper, etc
2 cups beef stock

Marinate meat (optional, not necessary with better cuts).
Season liberally and lace with garlic cloves by making incisions,
and placing whole cloves deep into the meat.
Grease a baking pan, and fill with a thick bed of onions,

celery, green onions, and parsley.
Place roast on top with fat side up.
Place uncovered in 500&#65533; oven for 20 minutes, reduce oven to 325&#65533;.
Bake

whole chickens
for frying before you go for the real thing.
Whole chicken is much more efficient and inexpensive than buying pieces.

1 tiny human, cut into pieces
2 cups flour
Onion, garlic
Salt
pepper
garlic powder
cayenne pepper
hot sauce, etc.
Oil for frying

Mix milk, eggs, hot sauce in a bowl, add chopped onion and garlic.
Season the meat liberally, and marinate for several hours.
Place seasoned flour in a paper or plastic shopping bag,
drop pieces in a few a time, shake to coat thoroughly,
then deep fry in hot oil (350�) for about 15 minutes.
Drain and place on paper towels.

Miscarriage with Mustard Greens

Why waste it? Otherwise, and in general, use ham or salt pork to season greens.
The technique of smothering greens can be used with many vegetables;
green beans work especially well. Meat is not necessary every day, don?t
be afraid to alter any dish to vegetarian tastes.

1 premature baby, born dead
Large bunch of mustard greens
2 white onions, 1 cup chopped celery
Vegetable oil (or hog fat)
Salt, pepper, garlic, etc.

Lightly brown onions, celery, garlic and meat in large heavy pot.
Add a little water and the greens (which should be thoroughly cleaned and washed).
Smother slowly for at least 2 hours, adding small amounts of water

```
with butter, oil and flour,
brown vegetables in the roux, then add chicken stock and
allow to simmer for 20 minutes.
Add the patties or stuffed heads, and some loose crawfish,
lobster, long piglet, or what have you.
Cook on low for 15 minutes, then allow it to set for at least
15 minutes more.
Serve over steamed rice; this dish is very impressive!

Stuffed Cabbage Rolls

Babies really can be found under a cabbage leaf -
or one can arrange for ground beef to be found there instead.

8 large cabbage leaves
1 lb. lean ground newborn human filets, or ground chuck
Onions
peppers
celery
garlic
soy sauce
salt pepper, etc
Olive oil
breadcrumbs
Tomato Gravy (see index)
```

Boil the cabbage leaves for 2 minutes to soften.
In skillet, brown the meat in a little olive oil,
then add onions, peppers, and celery (all chopped finely)
and season well.
Place in a large bowl and cool.
Add seasoned breadcrumbs and a little of the tomato gravy,
enough to make the mixture pliable.
Divide the stuffing among the cabbage leaves then roll.
Place seam down in a baking pan.
Ladle tomato gravy on top,
and bake at 325° for 30 - 45 minutes.

```
Umbilical Cordon Bleu

Nothing is so beautiful as the bond between mother and child,
so why not consume it?
Children or chicken breasts will work wonderfully also.
```

4 whole umbilical chords (or baby breasts, or chicken breasts)
4 thin slices of smoked ham, and Gruyere

secret to great meatballs, is to use very lean meat.

1 lb. ground flesh; human or pork
3 lb. ground beef
1 cup finely chopped onions
7 - 12 cloves garlic
1 cup seasoned bread crumbs
 cup milk, 2 eggs
Oregano
basil
salt
pepper
Italian seasoning, etc.
Tomato gravy (see index)
Fresh or at least freshly cooked spaghetti or other pasta

Mix the ground meats together in a large bowl,
then mix each of the other ingredients.
Make balls about the size of a baby?s fist
(there should be one lying around for reference).
Bake at 400for about 25 minutes -
or you could fry them in olive oil.
Place the meatballs in the tomato gravy, and simmer for several hours.
Serve on spaghetti.
Accompany with green salad, garlic bread and red wine.

Newborn Parmesan

This classic Sicilian cuisine can easily be turned into Eggplant Parmesan
If you are planning a vegetarian meal. Or you could just as well use veal -
after all, you have to be careful - Sicilians are touchy about their young
family members...

6 newborn or veal cutlets
Tomato gravy (see index)
4 cups mozzarella, 1cup parmesan, 1cup romano
Seasoned bread crumbs mixed with
parmesan
romano
salt
pepper
oregano
garlic powder
chopped parsley

Flour
eggwash (eggs and milk)
Peanut oil for frying.

Pound the cutlets.
Dredge in flour, eggs, then the bread crumb mixture.
Fry till golden brown in 350° peanut oil.
In a baking pan, place a layer of gravy,
then one of meat, gravy, and cheese.
Another layer each of meat, gravy, and cheese.
Then bake at 350° for 45 minutes.
Serve on hot pasta with romano cheese.

Southern Fried Small-fry

Tastes like fried chicken, which works just as well.
In fact you may want to practice cutting up whole chickens
for frying before you go for the real thing.
Whole chicken is much more efficient an

necessary every day, don?t
be afraid to alter any dish to vegetarian tastes.

1 premature baby, born dead
Large bunch of mustard greens
2 white onions, 1 cup chopped celery
Vegetable oil (or hog fat)
Salt, pepper, garlic, etc.

Lightly brown onions, celery, garlic and meat in large heavy pot.
Add a little water and the greens (which should be thoroughly cleaned and washed).
Smother slowly for at least 2 hours, adding small amounts of water
when it starts to stick.
Stir frequently.
When ready - serve with rice, grilled smoked sausage, green salad, and iced tea.
Coffee and apple pie then brandy.

Maternity Ward Pot Luck Dinner

If you can?t get anything fresh from the hospital, nursery, or morgue;
you can at least get rid of all the leftovers in your refrigerator.

1 - 2 lbs. cubed meat (human flesh, chicken, turkey, beef...)
1 -2 lbs. coarsely chopped vegetables
(carrots, potatoes, turnips, cauliflower, cabbage...)
Bell pepper
onions
garlic
ginger
salt pepper, etc.
Olive oil
butter

Brown the meat and some chopped onions, peppers, and garilic in olive oil,
place in baking dish, layer with vegetables seasoning and butter.
Bake at 325° for 30 - 45 minutes.
Serve with hot dinner rolls, fruit salad and sparkling water.

B°b° Buffet 1

Show off with whole roasted children replete with apples in mouths -
and babies? heads stuffed with wild rice. Or keep it simple with a
hearty main course such as stew, lasagna, or meat loaf.

Some suggestions

Pre-mie pot pies, beef stew, leg of lamb, stuffed chicken, roast pork spiral ham, Cranberry

Roast Leg of Amputee

By all means, substitute lamb or a good beef roast if the haunch
it is in any way diseased. But sometimes surgeons make mistakes,
and if a healthy young limb is at hand, then don?t hesitate to cook
it to perfection!

1 high quality limb, rack, or roast
Potatoes, carrot
Oil
celery
onions
green onions
parsley
garlic
salt, pepper, etc
2 cups beef stock

Marinate meat (optional, not necessary with better cuts).
Season liberally and lace with garlic cloves by making incisions,
and placing whole cloves deep into the meat.
Grease a baking pan, and fill with a thick bed of onions,
celery, green onions, and parsley.
Place roast on top with fat side up.
Place uncovered in 500° oven for 20 minutes, reduce oven to 325°.
Bake till medium rare (150°) and let roast rest.
Pour stock over onions and drippings, carve the meat and
place the slices in the au jus.

Bisque à l?Enfant

Honor the memory of Grandma with this dish by utilizing her good
silver soup tureen and her great grandchildren (crawfish, crab or
lobster will work just as well, however this dish is classically
made with crawfish).

Stuffed infant heads, stuffed crawfish heads, stuffed crab or lobster shells;
make patties if shell or head is not available
(such as with packaged crawfish, crab, or headless baby).
Flour
oil
onions
bell peppers
garlic salt, pepper, etc.
3 cups chicken stock
2 stick

```
cold water
1 egg beaten
```

Make the stuffing:
Marinate the flesh in a mixture of soy and teriyaki sauces
then stir fry in hot oil for till brown - about 1 minute, remove.
Stir-fry the vegetables.
Put the meat back into the wok and adjust the seasoning.
De-glaze with sherry, cooking off the alcohol.
Add broth (optional) cook a few more minutes.
Add the cornstarch, cook a few minutes till thick,
then place the stuffing into a colander and cool;
2 hours
Wrap the rolls:
Place 3 tablespoons of stuffing in the wrap, roll tightly -
corner nearest you first, fold 2 side corners in,
wrap till remaining corner is left.
Brush with egg, seal, and allow to sit on the seal for
a few minutes.
Fry the rolls:
325 if using egg roll wraps, 350 for spring roll wraps.
Deep fry in peanut oil till crispy golden brown, drain on paper towels.

```
Lemon Neonate

Turkey serves just as well, and in fact even looks a bit like a
well-dressed baby. By the time you turn the child?s breast into
cutlets, it will be indistinguishable. The taste of young human,
although similar to turkey (and chicken) often can be wildly
different depending upon what he or

as well.
In fact you may want to practice cutting up whole chickens
for frying before you go for the real thing.
Whole chicken is much more efficient and inexpensive than buying pieces.

1 tiny human, cut into pieces
2 cups flour
Onion, garlic
Salt
pepper
garlic powder
cayenne pepper
hot sauce, etc.
Oil for frying

Mix milk, eggs, hot sauce in a bowl, add chopped onion and garlic.
Season the meat liberally, and marinate for several hours.
Place seasoned flour in a paper or plastic shopping bag,
drop pieces in a few a time, shake to coat thoroughly,
then deep fry in hot oil (350�) for about 15 minutes.
Drain and place on paper towels.

Miscarriage with Mustard Greens

Why waste it? Otherwise, and in general, use ham or salt pork to season greens.
The technique of smothering greens can be used with many vegetables;
green beans work especially well. Meat is not necessary every day, don?t
be afraid to alter any dish to vegetarian tastes.

1 premature baby, born dead
Large bunch of mustard greens
2 white onions, 1 cup chopped celery
Vegetable oil (or hog fat)
Salt, pepper, garlic, etc.

Lightly brown onions, celery, garlic and meat in large heavy pot.
Add a little water and the greens (which should be thoroughly cleaned and washed).

pork, lamb,
poultry, and vegetables; just about anything can be grilled, and young humans
are no exception!

High quality marinade (Teriyaki and garlic perhaps)
1 inch cubes of tender meat, preferably from the nursery
Onions
bell peppers
Wooden or metal skewers

Marinate the meat overnight.
Get the grill good and hot while placing meat, vegetables, and
fruit such as pineapples or cherries on the skewers.
Don?t be afraid to use a variety of meats.
Grill to medium rare,
serve with garlic cous-cous and saut&#65533;ed asparagus.
Coffee and sherbet for desert then walnuts, cheese, and port.
Cigars for the gentlemen (and ladies if they so desire)!

Crock-Pot Crack Baby

When the quivering, hopelessly addicted crack baby succumbs to death,
get him immediately butchered and into the crock-pot, so that any
remaining toxins will not be fatal. But don?t cook it too long,
because like Blowfish, there is a perfect medium between the poisonous
and the stimulating. Though it may not have the same effect on your
guests, a whole chicken cooked in this fashion is also mighty tasty.

1 newborn - cocaine addicted, freshly expired, cleaned and butchered
Carrots
onions
leeks
celery
bell pepper
potatoes
Salt
pepper
garlic, etc
4 cups water

Cut the meat into natural pieces and brown very well in olive oil,
remove, then brown half of the onions, the bell pepper,

quality beef or pork roasts (it is cheaper and better to
cut up a whole roast than to buy stew meat).

1 stillbirth, de-boned and cubed
&#65533; cup vegetable oil
2 large onions
bell pepper
celery
garlic
&#65533; cup red wine
3 Irish potatoes
2 large carrots

This is a simple classic stew that makes natural gravy,
thus it does not have to be thickened.
Brown the meat quickly in very hot oil, remove and set aside.
Brown the onions, celery, pepper and garlic.
De-glaze with wine, return meat to the pan and season well.
Stew on low fire adding small amounts of water and
seasoning as necessary.
After at least half an hour, add the carrots and potatoes,
and simmer till root vegetables break with a fork.
Cook a fresh pot of long grained white rice.

Pre-mie Pot Pie

When working with prematurely delivered newborns (or chicken) use sherry;
red wine with beef (buy steak or roast, do not pre-boil).

Pie crust (see index)
Whole fresh pre-mie; eviscerated, head, hands and feet removed
Onions, bell pepper, celery
&#65533; cup wine
Root vegetables of choice (turnips, carrots, potatoes, etc) cubed

Make a crust from scratch - or go shamefully to the frozen food section
of your favorite grocery and select 2 high quality pie crusts (you
will need one for the top also).
Boil the prepared delicacy until the meat starts to come o

cook uncovered till thermometer reads 190&#65533;,
about another hour.

Pro-Choice Po-Boy

Soft-shelled crabs serve just as well in this classic southern delicacy.
The sandwich originated in New Orleans, where an abundance of abortion clinics
thrive and hot French bread is always available.

2 cleaned fetuses, head on
2 eggs
1 tablespoon yellow mustard
1 cup seasoned flour
oil enough for deep frying
1 loaf French bread
Lettuce
tomatoes
mayonnaise, etc.

Marinate the fetuses in the egg-mustard mixture.
Dredge thoroughly in flour.
Fry at 375&#65533; until crispy golden brown.
Remove and place on paper towels.

Holiday Youngster

One can easily adapt this recipe to ham, though as presented,
it violates no religious taboos against swine.

1 large toddler or small child, cleaned and de-headed
Kentucky Bourbon Sauce (see index)
1 large can pineapple slices
Whole cloves

Place him (or ham) or her in a large glass baking dish, buttocks up.
Tie with butcher string around and across so that he looks like
he?s crawling.
Glaze, then arrange pineapples and secure with cloves.
Bake uncovered in 350&#65533; oven till thermometer reaches

160�.

Cajun Babies

Just like crabs or crawfish, babies are boiled alive!
You don?t need silverware, the hot spicy meat comes off in your hands.

6 live babies
1 lb. smoked sausage
4 lemons
whole garlic
2 lb. new potatoes
4 ears corn
1 box salt
crab boil

Bring 3 gallons of water to a boil.
Add sausage, salt, crab boil, lemons and garlic.
Drop potatoes in, boil for 4 minutes.
Corn is added next, boil an additional 11 minutes.
Put the live babies into the boiling water and cover.
Boil till meat comes off easily with a fork.

Oven-Baked Baby-Back Ribs

Beef ribs or pork ribs can be used in this recipe,
and that is exactly what your dinner guests will assume!
An excellent way to expose the uninitiated to this highly misunderstood
yet succulent source of protein.

2 human baby rib racks
3 cups barbecue sauce or honey glaze (see index)
Salt
black pepper
white pepper
paprika

Remove the silverskin by loosening from the edges,
then stripping off.
Season generously, rubbing the mixture into the baby?s flesh.
Place 1 quart water in a baking pan, the meat on a wire rack.
Bake uncovered in 250° oven for 1½ hours.
When browned, remove and glaze,
return to oven and bake 20 minutes more to form a glaze.
Cut ribs into individual pieces and serve with extra sauce.

Fresh Sausage

If it becomes necessary to hide the fact that you are eating
human babies, this is the perfect solution.
But if you are still paranoid, you can substitute pork butt.

5 lb. lean chuck roast
3 lb. prime baby butt
2 tablespoons each:
salt
black, white and cayen

GAD the cost of that bottle!
A Svetlana 4CX800 is a LOT cheaper.
Many would recommend the 4Cx400A for the power level he wants
but you can (strangly enough) buy the 4CX800's for about the
same price as the 4CX400As. These tetrodes are usually run
passive grid driven (IE: 50 ohm grid resistor) but they can
also be run cathode driven. NOTE: this does not mean grounded
grid since both grids receive normal dc voltages are are grounded
ONLY for RF (IE: with capacitors).
BTW you can do the same thing with good old 4CX250's and 4X150's
if you can find good ones cheap surplus.

them in olive oil.
Place the meatballs in the tomato gravy, and simmer for several hours.
Serve on spaghetti.
Accompany with green salad, garlic bread and red wine.

Newborn Parmesan

This classic Sicilian cuisine can easily be turned into Eggplant Parmesan
If you are planning a vegetarian meal. Or you could just as well use veal -
after all, you have to be careful - Sicilians are touchy about their young
family members...

6 newborn or veal cutlets
Tomato gravy (see index)
4 cups mozzarella, 1cup parmesan, 1cup romano
Seasoned bread crumbs mixed with
parmesan
romano
salt
pepper
oregano
garlic powder
chopped parsley
Flour
eggwash (eggs and milk)
Peanut oil for frying.

Pound the cutlets.
Dredge in flour, eggs, then the bread crumb mixture.
Fry till golden brown in 350° peanut oil.
In a baking pan, place a layer of gravy,
then one of meat, gravy, and cheese.
Another layer each of meat, gravy, and cheese.
Then bake at 350° for 45 minutes.
Serve on hot pasta with romano cheese.

Southern Fried Small-fry

Tastes like fried chicken, which works just as well.
In fact you may want to practice cutting u

be used in this recipe,
and that is exactly what your dinner guests will assume!
An excellent way to expose the uninitiated to this highly misunderstood
yet succulent source of protein.

2 human baby rib racks
3 cups barbecue sauce or honey glaze (see index)
Salt
black pepper
white pepper
paprika

Remove the silverskin by loosening from the edges,
then stripping off.
Season generously, rubbing the mixture into the baby?s flesh.
Place 1 quart water in a baking pan, the meat on a wire rack.
Bake uncovered in 250? oven for 1? hours.
When browned, remove and glaze,
return to oven and bake 20 minutes more to form a glaze.
Cut ribs into individual pieces and serve with extra sauce.

Fresh Sausage

If it becomes necessary to hide the fact that you are eating
human babies, this is the perfect solution.
But if you are still paranoid, you can substitute pork butt.

5 lb. lean chuck roast
3 lb. prime baby butt
2 tablespoons each:
salt
black, white and cayenne peppers
celery salt
garlic powder
parsley flakes
brown sugar
1 teaspoon sage
2 onions
6 cloves garlic
bunch green onions, chopped

Cut the children?s butts and the beef roast into pieces
that will fit in the grinder.
Run the meat through using a 3/16 grinding plate.
Add garlic, onions and seasoning then mix well.

Add just enough water for a smooth consistency, then mix again.
Form the sausage mixture into patties or stuff into natural casings.

Stillborn Stew

By definition, this meat cannot be had altogether fresh,
but have the lifeless unfortunate available immediately after delivery,
or use high quality beef or pork roasts (it is cheaper and better to
cut up a whole roast than to buy stew meat).

1 stillbirth, de-boned and cubed
cup vegetable oil
2 large onions
bell pepper
celery
garlic
cup r

hi,

I am thinking about homebrewing a little digital packet transmitter for 233.6MHz to telemeter some data back from a model aircraft (no not radio control). It looks like thats a good freq for packet and it seems to be very quite on my scanner.

I was looking at VHF versus .. say 900MHz to save power and keep the batteries small. Perhaps a half a watt output max.

Do I understand correctly that since 233 is a quarter of 900MHz, it appears the rf loss will be about 12db less (simple free space) than if I went to 900, and thus it would take 16 times as much power at 900MHz to achieve the same distance?

I know that the higher freq would take more power but 1/2 watt versus 8 watts seems like a big difference.

Thanks in advance for the brain check. A

Alien-

At these frequencies, propagation is most likely limited to line-of-sight. If your aircraft flies over the horizon, it won't matter how much power the transmitter has.

If you do the math, I think you will find line-of-sight distances of many miles are achievable with relatively low power, assuming the antennas maintain a favorable orientation. If you couldn't maintain the orientation, or if the aircraft was tumbling or spinning, you would need many dB of link margin to be able to maintain the link.

Yes, there is a 20 log F factor that describes the propagation loss. Assuming the same type of antenna, it is related to wavelength in that the effective "capture area" of the receive antenna is related to wavelength. The transmitted signal will have a power density of so many watts per square meter when it reaches the receive antenna. Power received is the product of power density and antenna effective capture area, assuming you have a favorable relative polarization (orientation) of the two antennas.

The 233 frequency seems appropriate for what you want to do as far as propagation characteristics are concerned. However, here in the US, it is in the 225 to 395 MHz military communications band that includes government and civilian aircraft communications among others. It would be a good idea to coordinate use of the frequency with the closest government or military frequency manager. If not, you could interfere with aircraft operations you can't even hear from your location, not to mention possible loss of your aircraft!

Fred, thanks for the reply, the 233MHz was my finger fumble!, I
meant to type 223MHz which is out of the way of aircraft
communications and is in the digital/packet band plan of the 1.25m
band. A

Sure looks complex for a circuit that only delivers 10W and 10dB gain at 14 MHz. Also, the common-collector configuration ("emitter follower") is notorious for becoming an oscillator when driving reactive loads.

What's the advantage of this circuit supposed to be?

While the collector is grounded for RF the circuit is NOT an emitter
follower. The drive is impressed via a link to the E-B of the
transistor and taken off the emitter not the base. A two port
analysis makes the characteristic behavour similar to
common emitter. The low gain was devices of the time rather
than the circuit itself.

I've seen this used in older Aircraft comm radios, at least two
different older solid state CB (ca-1969) and varios other places.

It's weakness is rather high rf feedthrough making CW and AM
system require keying the previous stage (driver) or there will be
poor keying and/or modulation. Also reflected RF (load mismach)
was reflected back to the driver resulting in poor operation under
less than optimum loading.

The upside was it made it easier to cope with the fact that the
collector was a high capacitance to a heatsink for RF.

Using modern devices and circuit techniques makes this a less
than desireable design.

It's not actually common-collector. The input is applied between the
base and emitter, and the output extracted between the emitter (ignoring
ballast resistors) and collector. It's an ordinary common emitter
amplifier but with the collector grounded.

Unlike the emitter follower, which is almost guaranteed to become
unstable with sufficiently large capacitive loads, this circuit is
devoid of feedback external to the transistor. The circuit should be
fairly stable assuming the tank circuit is well behaved at all
frequencies up to the transistor Fc.

> What's the advantage of this circuit supposed to be?

Insulator between collector and heatsink is unnecessary.

4331. FET amplifier (theory != measurement)

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-12-27 23:12:42 UTC
From: Gary Morton <gary@alma.demon.co.uk>
Message-ID: <KF0Ad.7951$Ar5.7318@text.news.blueyonder.co.uk>
Source record: 21315

I've been struggling to really understand how FET buffers and simple FET amplifiers work, since implementing a VCO buffer which didn't work.

I've recently read the Jan 2005 issue of Practical Wireless in which there is an article regarding FET amplifiers.

Tonight I selected a 2N3819 FET and made various Vgs vs Id measurements and plotted them in a table and a graph. I got the expected curve. Vpgs was around -4V and Idss was 13mA.

I chose an operating point from the table of Id=4.1mA and Vgs=-2V and from this calculated Rs and chose the nearest standard value of 470ohm.

I then breadboarded (in a 0.1" plug in board) a simple FET amplifier circuit starting with Rg, Rs, the FET and an input decoupling capacitor of 1nF only. I used a meter to measure Id. It was 4.3mA - near enough to the expected value given the choice of the resistor. The source voltage was 2.0V. All as expected.

I then added Rd. Since Vdd was 10V (from a PSU and decoupled on the breadboard with 220uF and 0.1uF) I selected 10-((10-2)/2) = 6V for the drain voltage to allow a symmetrical output voltage swing. Rd was calculated and a value of 1k was chosen.

Adding this component slightly changed the bias values. I assume that this is because the Vgs vs Id function changes with Vdd which has now lowered from the 10V used when the plot was made to the current value of around 5.7V.

I then connected up a signal generator and set the frequency to 9MHz. For an input swing of 2V pk-to-pk the output voltage was virtually the same. This is where I have problems understanding exactly what is happening. I know that since Rs is not decoupled there is negative feedback and Vgs will vary slightly from the quiescent value. In doing so Id will change which should be the same as Is which should modulate the output voltage. I have been trying to visualise how the operating point is moving on the Vgs vs iD graph, but I am not getting it.

When I add a decoupling capacitor of 1nF across Rs, I think that I understand things better. Since the source voltage is now fixed for RF as the input voltage changes Vgs is directly modulated and modulates Id. The PW article explains that the gain should be gm * Rd. Using the table gm should be around 3.2mA/V for the bias values. Calculations say that the gain should be 0.0032 * 1000 = 3.2, but using a scope I see a gain of slightly over 2. Even for an input of 2V pk-to-pk the output waveform is pretty good.

I'm puzzled with the discrepancy between measured values and calculated values. Could the difference in the drain voltage between making the measurements for the plot and the value used in the circuit be the reason? I

haven't gone back to re-plot the graph.

The circuit gain was consistent from a few MHz upto around 15MHz when it dropped of considerably. Not bad for a breadboarded design connected with wires of a few inches long. I don't know upto what frequency a properly built circuit should operate upto.

I'm also thinking that I am at the limit of the input level that the circuit can take (although I can't increase the value as it is already the maximum from the sig gen). Since Vgs quiescent is -2V and Vpgs is -4V I suspect that Vgs is swinging from -4V to 0V.

My interest in the input range is more relevant for the FET source follower configuration. This was the one which originally failed due to trying to buffer to large a voltage swing taken directly from the oscillator tuned circuit. Again I was having difficulty figuring out just how large a voltage swing this circuit could buffer.

Any pearls of wisdom would be much appreciated.

I've read all the usual texts but it obviously hasn't quite sunk in!
I've also Googled for relevant information, but I've yet to find a clearly written explanation that I can understand 100%. Some texts make assumptions or omit key details.

regards...

Just had some friends over to play with a newly completed Montreal Fox
and a TOA antenna -- much fun, particularly the last hunt where their
kid buried it under the leaves and we stumbled around the same 10'x10'
patch of ground for 15 minutes before we found it.

That's correct -- the FET isn't a perfect current source.

The presence of the source resistor causes Vgs to change as Id changes,

but in the opposite direction. That is, as Id increases, Vs increases, causing Vgs to become more negative, which tends to decrease Id. This is classical negative feedback, which nearly always tends to reduce gain. The voltage gain should be about Rd / (Rs + 1/gm). Assuming that your value of gm is correct, 1/gm = 312.5 ohms. This should result in a voltage gain of about 1.3. Explanations for the difference between this value and what you saw might be a misestimation of gm, or the shunting effect of the effective FET drain resistance which is in parallel with Rd. The effective drain resistance, incidentally, is simply the reciprocal of the slope of the Id line on the Id vs Vd graph at the operating point. Sorry, I can't help you with visualizing the operating point movement on the Id/Vd graph with Rd present.

> 2V pk-to-pk the output waveform is pretty good.

Now, Rs is zero as far as the signal is concerned, so your voltage gain becomes approximately Rd / (1/gm) = gm * Rd. I suspect that your gm estimation is high. Try also including FET drain resistance to see if that won't get you closer to the measured value.

Bot notice also that when you're dealing with a large signal, the variation of gm over the cycle becomes significant. This means that you have different gain during each part of the signal cycle, resulting in signal distortion. This will also impact your apparent gain.

>

FET amplifiers work well into the VHF and even UHF range, but with lower values of resistance and different topologies such as common base. Device capacitance, both fundamental and multiplied by Miller effect, become limiting factors, as do case parasitics.

> I'm also thinking that I am at the limit of the input level that the
> circuit can take (although I can't increase the value as it is
> already the maximum from the sig gen). Since Vgs quiescent is -2V and
> Vpgs is -4V I suspect that Vgs is swinging from -4V to 0V.

That's hard to say, since pinchoff voltage isn't a hard limit. In fact, I suspect that it's more like -8 to -10 volts for your device, as typically measured at 0.1 or 1 nA Id. But the distortion will get worse and worse and begin looking like a soft clipping at some point.

>
> My interest in the input range is more relevant for the FET source
> follower configuration. This was the one which originally failed due
> to trying to buffer to large a voltage swing taken directly from the
> oscillator tuned circuit. Again I was having difficulty figuring out
> just how large a voltage swing this circuit could buffer.

Source followers have an output resistance of around 1/gm, which is typically in the range of a few hundred ohms for small signal JFETs. This is very high compared to a bipolar transistor, and so a source follower will badly attenuate a signal delivered to, say, a 50 ohm load, unless a transformer is used so the source follower sees a higher load impedance. They're suitable only for a limited number of applications, and not nearly so generally useful as a bipolar emitter follower.

> Any pearls of wisdom would be much appreciated.

You're doing a great job of learning about how these devices work -- keep it up. Load line analysis can be a great tool, as you've found, to visualize how the various voltages and currents interact. But you have to be aware that there can be a very great difference between one individual device and another, even with the same part number -- for example, a 10:1 range of possible Idss isn't unusual. So the curves you get from one device may be very different from ones you get from the next one you pick from the drawer. This makes it a real challenge to design circuits with FETs which can be duplicated. There's no problem designing a circuit to work with a particular, individual device, but don't expect someone else to build the same circuit and get the same results. It can, of course, be done, for certain types of circuits, often using considerable feedback and sacrificing gain for repeatability. But it does take a pretty deep understanding of the interrelationship among the parameters. And you're on your way to getting that.
>
> I've read all the usual texts but it obviously hasn't quite sunk in!
> I've also Googled for relevant information, but I've yet to find a

> make assumptions or omit key details.

For the level of understanding you're looking for, I'd avoid the technician-level books and get some textbooks written for electronics courses in an Electrical Engineering curriculum. Mine are awfully dated, but I'm sure there are plenty of newer ones available. I also suggest that you get a copy of SPICE and learn to use it. It'll allow you to poke around in a circuit where your 'scope can't go, to get a better understanding of what's happening. You can also do such things as build a transistor model piece by piece to see what effect each part has -- you'll be surprised how well a very simple model can often work. And

finally, you can see how much harm your long leads and other layout techniques might or might not be having on the results. It's a terrific learning tool.

You must not have:

(1) Visited the web link.

(2) Realized that a '6' call is going to be California.

This particular swap is in Lawndale, CA, southwest of Los Angeles.

1) It does not make sense for me (or anyone) to visit the link of
every one of these in case it is nearby. Posters should realize that
their message is going to people all over the world, and provide some
details.

2) There are a number of hams who have moved since receiving their
license, who keep their original call, so that is not completely
useful for location.

Even so, I hear California is a large place. Just adding "Los Angeles
area" or whatever to the original message would have made it far more
useful for potential visitors.

Free quick easy money Amazing !!!!!!!!!!!!
Date: 22 Dec 04

Comments

HOW TO TURN $6 INTO $6,000!!!!!! READING THIS COULD CHANGE YOUR LIFE! I found this on a bulletin board and decided to try it. A little while back, I was browsing through newsgroups, just like you are now, and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of $6.00! So I thought, Yeah right, this must be a scam,but like most of us, I was curious, so I kept reading. Anyway, it said that you send $1.00 to each of the 6 names and address stated in the article. You then place your own name and address in the bottom of the list at #6, and post the article in at least 200 newsgroups. (There are thousands) No catch, that was it. So after thinking it over, and talking to a few people first, I thought about trying it. I figured: what have I got to lose except 6 stamps and $6.00, right? Then I invested the measly $6.00. Well GUESS WHAT!!... within 7 days, I started getting money in the mail! I was shocked! I figured it would end soon, but the money just kept coming in. In my first week, I made about $25.00. By the end of the second week I had made a total of over $1,000.00! In the third week I had over $10,000.00 and it's still growing. This is now my fourth week and I have made a total of just over $42,000.00 and it's still coming in rapidly. It's certainly worth $6.00, and 6 stamps, I have spent more than that on the lottery!! Let me tell you how this works and most importantly, why it works....Also, make sure you print a copy of this article NOW, so you can get the information off of it as you need it. I promise you that if you follow the directions exactly, that you will start making more money than you thought possible by doing something so easy! Suggestion: Read this entire message carefully! (print it out or download it.) Follow the simple directions and watch the money come in! It's easy. It's legal. And, your investment is only $6.00 (Plus postage) IMPORTANT: This is not a rip-off; it is not indecent; it is not illegal; and it is virtually no risk - it really works!!!! If all of the following instructions are adhered to, you will receive extraordinary dividends. PLEASE NOTE: Please follow these directions EXACTLY, and $50,000 or more can be yours in 20 to 60 days. This program remains successful because of the honesty and integrity of the participants. Please continue its success by carefully adhering to the instructions. You will now become part of the Mail Order business. In this business your product is not solid and tangible, it's a service. You are in the business of developing Mailing Lists. Many large corporations are happy to pay big bucks for quality lists. However, the money made from the mailing lists is secondary to

the income which is made from people like you and me asking to be included in that list. Here are the 4 easy steps to success: STEP 1: Get 6 separate pieces of paper and write the following on each piece of paper;PLEASE PUT ME ON YOUR MAILING LIST. Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelope (to prevent thievery). Next, place one paper in each of the 6 envelopes and seal them. You should now have 6 sealed envelopes, each with a piece of paper stating the above phrase, your name and address, and a $1.00 bill. What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate service and you are paying for it! Like most of us I was a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the U.S. Post Office (1-800-725-2161) and they confirmed that it is indeed legal! Mail the 6 envelopes to the following addresses:

#1)Randall Hines 22 Stature Dr. Newark
DE 19713

#2) Mike Sharrer 921 West State St. Coopersburg PA 18036

#3) Jeffrey Hyun 17414Stark Ave Cerritos,CA 90703

#4) James Adair the third 22 Over Rd. Feasterville PA 19053

#5) TSR Solutions 15907 Golden Eye CT Parker CO 80134

#6) Daryl L. 6063 Roosevelt Blvd Apt# 216 Philadelphia PA 19149

STEP 2: Now take the #1 name off the list that you see above, move the other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number 6 on the list. STEP 3: Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups. (I think there are close to 24,000 groups) All you need is 200, but remember, the more you post, the more money you make! This is perfectly legal! If you have any doubts, refer to Title 18 Sec. 1302 & 1341 of the Postal lottery laws. Keep a copy of these steps for yourself and, whenever you need money, you can use it again, and again. PLEASE REMEMBER that this program remains successful because of the honesty and integrity of the participants and by their carefully adhering to the directions. Look at it this way. If you are of integrity, the program will continue and the money that so many others have received will come your way. NOTE: You may want to retain every name and address sent to you, either on a computer or hard copy and keep the notes people send you. This VERIFIES that you are truly providing a service. (Also, it might be a good idea to wrap the $1 bill in dark paper to reduce the risk of mail theft.) So, as each post is downloaded and the directions carefully followed, six members will be reimbursed for their participation as a List Developer with one dollar each. Your name will move up the list geometrically so that when your name reaches the #1 position you will be receiving thousands of dollars in CASH!!! What an opportunity for

only $6.00 ($1.00 for each of the first six people listed above) Send it now, add your own name to the list and you're in business! ---DIRECTIONS ----- FOR HOW TO POST TO NEWSGROUPS---------- Step 1) You do not need to re-type this entire letter to do your own posting. Simply put your cursor at the beginning of this letter and drag your cursor to the bottom of this document, and select 'copy' from the edit menu. This will copy the entire letter into the computer's memory. Step 2) Open a blank 'notepad' file and place your cursor at the top of the blank page. From the 'edit' menu select 'paste'. This will paste a copy of the letter into notepad so that you can add your name to the list. Step 3) Save your new notepad file as a .txt file. If you want to do your postings in different settings, you'll always have this file to go back to. Step 4) Use Netscape or Internet explorer and try searching for various newsgroups (on-line forums, message boards, chat sites, discussions.) Step 5) Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in the Subject, this will be the header that everyone sees as they scroll through the list of postings in a particular group, click the post message button. You're done with your first one! Congratulations...THAT'S IT! All you have to do is jump to different newsgroups and post away, after you get the hang of it, it will take about 30 seconds for each newsgroup! **REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200** That's it! You will begin receiving money from around the world within days! You may eventually want to rent a P.O.Box due to the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use, as long as the postman will deliver it. **JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.** Now the WHY part: Out of 200 postings, say I receive only 5 replies (a very low example). So then I made $5.00 with my name at #6 on the letter. Now, each of the 5 persons who just sent me $1.00 make the MINIMUM 200 postings, each with my name at #5 and only 5 persons respond to each of the original 5, that is another $25.00 for me, now those 25 each make 200 MINIMUM posts with my name at #4 and only 5 replies each, I will bring in an additional $125.00! Now, those 125 persons turn around and post the MINIMUM 200 with my name at #3 and only receive 5 replies each, I will make an additional $626.00! OK, now here is the fun part, each of those 625 persons post a MINIMUM 200 letters with my name at #2 and they each only receive 5 replies, that just made me $3,125.00!!! Those 3,125 persons will all deliver this message to 200 newsgroups with my name at #1 and if still 5 persons per 200 newsgroups react I will receive $15,625,00! With an original investment of only $6.00! AMAZING! When your name is no longer on the list, you just take the latest posting in the newsgroups, and send out another $6.00 to names on the list, putting your name at number 6 again. And start posting again. The thing to remember is: do you realize that thousands of people all over the world are joining the internet and reading these articles everyday?, JUST LIKE YOU are now!! So, can you afford $6.00 and see if it really works?? I think so... People have said, &quote;what if the plan is played out and no one sends you the money?

So what! What are the chances of that happening when there are tons of new honest users and new honest people who are joining the internet and newsgroups everyday and are willing to give it a try? Estimates are at 20,000 to 50,000 new users, every day, with thousands of those joining the actual internet. Remember: play FAIRLY and HONESTLY and this will really work.

Folks - you can also just look at the headers and can tell immediately if it's a forgery:

- posting IP
- path
- user agent

The combination of those three will give each of us a unique I.D. as to our authenticity :-)

For me, it will always read:

- posting IP, though dynamic, always traceable to Telus.net
- Again, will always originate from Telus
- Pan 0.11.2/Unix, there's probably less than 15 people on the entire Telus ISP network that use that combination of Linux/Pan version.

Behold, Gregg signalled from keyed 4-1000A filament:

Sorry for the messy post, I hate auto wrap!

Let's try that again....

- posting IP, though dynamic, always traceable to Telus.net
- Again,will always originate from Telus
- Pan 0.11.2/Unix, there's probably less than 15 people on
the entire Telus ISP network that use that combination of
Linux/Pan version.

Hi all,
I received e-mail this evening telling me that it is nice to have Harry's Homebrew Homepages back again!! They never went anywhere. I know that the number of visitors has declined, but I am still very much alive and kicking.

The URL is http://web.telia.com/~u85920178/

I had assumed that http://web.telia.com/~u85920178/ was so difficult to remember that a few visitors had forgotten me, but over last year I have got a new messageboard at http://amazingforums.com/forum2/SM0VPO/forum.html and introduced a couple of new projects, including a 400mW 88-108MHz PA (works well at 50MHz, 70MHz and 144MHz), and a VHF gain antenna, with calculator, that can be built and tested within about 15 minutes (50MHz to 900MHz - works well on 144-432MHz and 446MHz).

My e-mail address sm0vpo(at)home(dot)se got100's of messages each time I logged on: 95% SPAM. I filled the mailbox and deleted the account from Outlook. After a year of messages bouncing I hope the spammers will have moved on and I can use it again. In the meantime you can write to me on oeieio(at)hotmail.com or the old trusty harryvpo(at)hotmail.com (if the SPAM there continues I may close harryvpo).

New projects for the new year? Yes. Loads of ideas, some already in progress, including:
- Article about static electricity - will include a bit of humour
- Stereo encoder
- Tuneable VHF NBFM Receiver for 145-156MHz
(or any 1MHz chunk from 50MHz to 500MHz)
- Tuneable VHF NBFM transmitter (---ditto---)
- Practical antenna info - how-to, with photo's
- Soldering video (15 minutes VCD) still on the list

BR Harry

4348. Direct conversion + DSP receiver for S-measurements?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-12-31 03:55:56 UTC
From: tf3kx@simnet.is

Hi:

I am looking for a HF receiver (1,8-30 MHz) that I can use to measure received signals and record the measurements into a PC for further analysis. I do own an Icom IC746 that provides S-meter data, but it has several shortcomings.

So, for example, I wonder if there are any new projects or kits around that are based on the R1/R2 direct conversion design, but with the addition of good quality DSP and a DDS oscillator? Something that would give me digitized signals from a "general coverage" box.

Kanga seems to offer an advanced version of the R2, but with an analog VFO and analog AF processing. Any other suggestions or pointers?
